ABSTRACT

Lead Federal Agency: U.S. Department of Energy (Western Area Power Administration; Loan Guarantee Program)

Lead State Agency: California Energy Commission

Cooperating Agency: U.S. Bureau of Land Management

Title: Draft Environmental Impact Statement/Staff Assessment for the Solar Reserve LLC Rice Solar Energy Project, Riverside County, California (DOE/EIS-0439)

Further Information: For information on the proposed Project, the EIS and general information about Western's transmission system, contact Ms. Liana Reilly, Western NEPA Document Manager, NEPA Document Manager, Western Area Power Administration, P.O. Box 281213, Lakewood, CO 80228-8213, telephone (800) 336-7288. For general information on the DOE NEPA process, please contact: Ms. Carol M. Borgstrom, Director, Office of NEPA Policy and Compliance (GC-54), U.S. Department of Energy, 1000 Independence Avenue, SW., Washington, DC 20585, telephone (202) 586-4600 or (800) 472-2756. For information on the DOE Loan Guarantee Program's involvement in the Project, contact Ms. Angela Colamaria, NEPA Document Manager, DOE Loan Guarantee Program, 1000 Independence Ave. SW, LP-10, Washington, DC 20585, telephone (202) 287-5387, or e-mail angela.colamaria@hq.doe.gov. For information on BLM's role with the Project or the possible CDCA Plan Amendment, contact Ms. Allison Shaffer, BLM Project Manager, Project Manager, Palm Springs South Coast Field Office, Bureau of Land Management, 1201 Bird Center Drive, Palm Springs, CA, 92262, telephone (760) 833-7100 or e-mail CAPSSolarRice@blm.gov.

For information on the California Energy Commission process, contact John Kessler, Project Manager, Siting, Transmission and Environmental Protection Division, California Energy Commission, 1516 Ninth Street, MS-15, Sacramento, CA 95814, telephone (916) 654-4679 or e-mail jkessler@energy.state.ca.us. Information on the California Energy Process may be also be found online at <http://www.energy.ca.gov/sitingcases/ricesolar/index.html>.

Abstract: Rice Solar Energy (RSE) has submitted an Application for Certification to the California Energy Commission for a proposed 150 megawatt (MW) solar electric power plant that would use concentrating solar "power tower" technology to capture the sun's heat to make steam, which would power a traditional steam turbine generator. The solar generation facility, located on privately owned land, would use an air cooled condenser (i.e., dry cooling technology) for power plant cooling. Rice Solar Energy, LLC (RSE) has applied to Western to interconnect the proposed Project to Western's transmission system. A new 10-mile long 230-kV generator tie-line would extend from the southern boundary of the solar facility boundary to a new substation to be constructed adjacent to Western's existing Parker-Blythe #2 transmission line. RSE also submitted an application to the DOE LGP seeking a guarantee for the proposed Project.

RSE has submitted a right-of-way (ROW) application to the BLM for the Project components (the generator tie-line, substation, access road, and fiber optic line) to be constructed on a total of approximately 12 acres of land managed by the BLM. The Project site is in an undeveloped area of the Sonoran Desert in eastern Riverside County, California, near State Route 62, approximately 40 miles northwest of Blythe, California, and 15 miles west of Vidal Junction, California, on lands managed by the BLM.

Comments on this Draft EIS should be sent to Ms. Liana Reilly at the Western address above. Comments must be postmarked no later than the expiration of the 90 day comment period announced in the U.S. Environmental Protection Agency's Notice of Availability for this Draft EIS.

EXECUTIVE SUMMARY

Testimony of John Kessler

INTRODUCTION

The proposed action evaluated within this Staff Assessment/Draft Environmental Impact Statement (SA/DEIS) is the construction and operation of the Rice Solar Energy Project (RSEP), a proposed solar-thermal generation facility. The RSEP power plant and a portion of the Generation Tie Line would be located on private land, and the remaining portion of the Tie Line would be on public lands managed by the Bureau of Land Management (BLM) in unincorporated eastern Riverside County, California. The interconnection to the electric transmission system would be to Western Area Power Administration's (Western's) Parker-Blythe #2 Transmission Line. The SA/DEIS represents a joint environmental review document developed by the California Energy Commission (Energy Commission), BLM and Western to evaluate potential impacts associated with the proposed action. The DEIS also functions as the environmental evaluation of a proposed amendment to BLM's California Desert Conservation Area (CDCA) Plan, which would identify the RSEP generation tie line within the Plan.

When considering a thermal-electric energy project of 50 megawatts or greater for licensing, the Energy Commission is the lead state agency for evaluating environmental impacts of a proposed licensing action under the California Environmental Quality Act (CEQA). The SA, the result of the Energy Commission staff's environmental evaluation process, is functionally equivalent to the preparation of an Environmental Impact Report.

Western, on behalf of the Department of Energy (DOE), is the lead federal agency evaluating environmental impacts of the proposed project under the National Environmental Policy Act (NEPA) as associated with the electrical interconnection to Western's transmission system. The proposed project is located partially on public lands managed by the BLM and would require a right-of-way grant and land use plan amendment to allow project use of those lands. For this reason, BLM is a cooperating agency in evaluating environmental impacts of the proposed project under NEPA, pursuant to an MOU between Western and BLM, and an MOU between DOE's Loan Guarantee Program (LGP) and BLM. The DEIS is the BLM's environmental evaluation of the potential impacts that could result from the authorization of the requested right-of-way and similarly serves as Western's environmental evaluation of the potential impacts that could result from the proposed electrical transmission interconnection. The LGP is also participating with Western in the preparation of this SA/DEIS as the project proponent has applied for a loan guarantee to fund the proposed project.

In August, 2007, the Energy Commission and BLM California Desert District (CDD) entered into a Memorandum of Understanding (MOU) to jointly develop the environmental analysis documentation for solar thermal projects which are under the jurisdiction of both agencies. The purpose of the MOU is to avoid duplication of staff efforts, share staff expertise and information, promote intergovernmental coordination, and facilitate public review. Consistent with the guidelines of the MOU, this document represents the Energy Commission's SA, as well as the BLM's and DOE's DEIS.

Following a 90-day public comment period, BLM and Western, on behalf of DOE, will issue a Final EIS.

For Energy Commission purposes, this SA/DEIS is a staff document that may be revised by staff based on comments received during a 30-day comment period. It is neither a document of the California Energy Commission Siting Committee, a draft decision by the Siting Committee, nor a Final Decision by the Energy Commission. Similarly, the SA/DEIS does not serve as a decision document that would be used by decision makers when considering approving the right-of-way grant by BLM or the interconnection to Western's transmission system.

PROJECT LOCATION AND DESCRIPTION

The applicant has proposed to locate the RSEP in the Mojave Desert, approximately 32 miles west of Parker, Arizona and approximately 40 miles northwest of Blythe, California in Riverside County, California. The nearest community is Vidal Junction, approximately 15 miles northeast. The site is adjacent to State Route 62 (SR-62), which parallels a portion of the Arizona-California Railroad and the Colorado River Aqueduct, near the junction of SR-62 and Blythe-Midland Road, and near the sparse remains of the abandoned town of Rice, California. The power plant would occupy 1,410 acres of a larger 2,560-acre parcel on private land located adjacent to, and immediately south of, SR-62, and would occupy about 99 acres of federal land managed by BLM associated with the generation tie line and new interconnection substation.

Approximately nine miles of the 10-mile long generation tie line would be located on public land administered by the BLM with the balance on private land. The electrical interconnection would be to Western's Parker-Blythe #2 161 kilovolt (kV) transmission line at a new substation located southeast of the power plant. RSEP would include fiber optic and/or microwave telecommunication facilities associated with the electrical interconnection to Western's facilities. The nearest community is Vidal Junction, approximately 15 miles northeast. Access to the site is directly from SR-62 (SR 2009a, Sections 1 and 2).

The proposed RSEP would be a concentrating solar thermal power plant development in which most of the power plant area consists of a field of heliostats (elevated mirrors guided by a tracking system) focusing solar energy on a solar receiver heat exchanger located on one centralized power tower. Each heliostat tracks the sun throughout the day and reflects the solar energy to the receiver. The project features thermal energy storage that allows solar energy to be captured throughout the day and retained in a liquid salt heat transfer fluid. When electricity is to be generated, the hot liquid salt is routed to a series of heat exchangers to heat water and produce steam. The steam is used to generate electricity in a conventional steam turbine cycle that would utilize an air-cooled condenser to minimize water consumption.

RSEP is designed to produce electricity at a capacity of 150 megawatts (MW) and annual energy of 450,000 megawatt-hours per year during periods of peak energy demands. The primary components of the 1,410 acre power plant site would include the heliostat field, a 653-foot high central tower and receiver, hot and cold liquid salt storage

tanks, a steam-turbine generator and associated equipment, a 20-cell air-cooled condenser, two on-site water wells, three evaporation ponds to capture and evaporate process wastewater, two storm water detention basins, an electrical switchyard, and associated administration and maintenance facilities (SR 2009a, Section 2). Please see the **Project Action/Proposed Project** section for a more details of the proposed project.

PUBLIC AND AGENCY COORDINATION

Both the Energy Commission's CEQA-equivalent process and the BLM's NEPA process provide opportunities for the public and other agencies to participate and consult in the scoping of the environmental analysis, and in the evaluation of the technical analyses and conclusions of that analysis. The following subsections describe the status of these outreach efforts.

Public Coordination

Both the Energy Commission's CEQA-equivalent process and the BLM's/Western's NEPA process provide opportunities for public participation in the scoping of the environmental analysis, and in the evaluation of the technical analyses and conclusions of that analysis. For the Energy Commission, this outreach program is primarily facilitated by the Public Adviser's Office (PAO). As part of the coordination of the environmental review process required under the Energy Commission/BLM California Desert District MOU and in coordination with Western, the agencies have jointly held public meetings and workshops which accomplish the respective public coordination objectives. This is an ongoing process that to date has involved the following efforts.

Libraries

The Application for Certification (AFC) was sent to local public libraries in Blythe and Desert Center, California and Parker, Arizona and at public libraries in Fresno, Eureka, San Diego and San Francisco, the California State Library, and the Energy Commission's library in Sacramento.

Outreach Efforts

The PAO's public outreach is an integral part of the Energy Commission's AFC review process. The PAO reviewed information provided by the applicant and also conducted its own outreach efforts to identify and locate local elected and certain appointed officials, as well as "sensitive receptors" (such as schools, community, cultural and health facilities and daycare and senior-care centers, as well as environmental and ethnic organizations). There were not any sensitive receptors identified within a six-mile radius of the proposed site for the project.

Notices for workshops and hearings have been and will continue to be distributed to those agencies, individuals, and businesses that are currently on or request to be placed on the project's mailing list. Notices were distributed for the Informational Hearing and Site Visit, which was conducted on January 25, 2010, in Blythe, California.

Coincident with the PAO's outreach efforts, BLM and Western solicited interested

members of the public and agencies through the NEPA scoping process. BLM and Western published a Notice of Intent to develop the EIS and amend the CDCA Plan in the Federal Register, Vol. 75, No. 59, pages 15427 - 15429, on March 29, 2010. BLM and Western conducted two Public Scoping meetings for the EIS in accordance with NEPA. The first of these was conducted on March 31, 2010 in Big River and the second was conducted on April 1, 2010 in Palm Desert.

During the process, the Energy Commission, BLM, Western and the applicant coordinated to conduct two workshops. The first was an Issue Resolution workshop which was held in Sacramento, California on March 19, 2010. The second was a Site Visit to Discuss Historical Resources conducted at the RSEP site on June 2, 2010. Both events were announced and made available to the public. The Energy Commission has also continued to accept and consider public comments.

Those agencies and individuals that have provided comments concerning the project have been considered in staff's analysis. This SA/DEIS provides agencies and the public with an opportunity to review the Energy Commission staff's analysis of the proposed project. Comments received on this SA/DEIS will be taken into consideration in preparing the subsequent project documents.

Energy Commission regulations require staff to notice, at a minimum, property owners within 1,000 feet of a project and 500 feet of a linear facility under its jurisdiction. This was done for the RSEP project.

The applicant's AFC, AFC Supplement, Responses to Data Requests, this SA/DEIS, and other project documents are located on the Energy Commission's website at <http://www.energy.ca.gov/sitingcases/ricesolar/index.html>.

ENVIRONMENTAL JUSTICE

Executive Order 12898, "Federal Actions to address Environmental Justice in Minority Populations and Low-Income Populations," focuses federal attention on the environment and human health conditions of minority communities and calls on federal agencies to achieve environmental justice as part of this mission. The order requires the USEPA and all other federal agencies (as well as state agencies receiving federal funds) to develop strategies to address this issue. The agencies are required to identify and address any disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority and/or low-income populations.

The purpose of the screening analysis is to determine whether a minority or low-income population exists within the potentially affected area of the proposed site. For all siting cases, Energy Commission staff conducts an environmental justice screening analysis in accordance with the "Final Guidance for Incorporating Environmental Justice Concerns in USEPA's National Environmental Policy Act (NEPA) Compliance Analysis" dated April 1998, which defined minority populations as either:

- a low-income and/or minority population of the affected area is greater than 50% of the affected area's general population; or

- the minority population percentage of the area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis.

California Statute, Section 65040.12 (c) of the Government Code, defines “environmental justice” to mean “fair treatment of people of all races, cultures, and incomes with respect to the development, adoption, implementation, and enforcement of environmental laws, regulations, and policies.” In light of the progress made by federal environmental agencies on environmental justice, the Energy Commission has examined federal guidelines pursuant to its desire to follow environmental justice principles for the environmental review of this project.

The steps recommended by these guidance documents to assure compliance with the Executive Order are: (1) outreach and involvement; (2) a screening-level analysis to determine the existence of a minority or low-income population; and (3) if warranted, a detailed examination of the distribution of impacts on segments of the population. Though the Federal Executive Order and guidance are not binding on the Energy Commission, staff finds these recommendations helpful for implementing this environmental justice analysis. Staff has followed each of the above steps for the following 11 sections in the FSA/DEIS: Air Quality, Hazardous Materials, Land Use, Noise, Public Health and Safety, Socioeconomics and Environmental Justice, Soils and Water, Traffic and Transportation, Transmission Line Safety/Nuisance, Visual Resources, and Waste Management.

According to the Census 2000 data there were five people within six miles of the proposed project site which resided within California. With one person (20%) of the total California residents classified as minority (see **SOCIOECONOMICS AND ENVIRONMENTAL JUSTICE FIGURE 1**), no census blocks within a six-mile radius of the proposed RSEP site contain minority populations greater than 50%. The agencies normally identify below-poverty-level population within the six-mile radius using Year 2000 U.S. Census block group data. However, for this project the poverty data would be inaccurate for the six-mile radius because the census block groups are so large that they include persons well beyond the six-mile radius and therefore, would misrepresent the poverty data within the six-mile radius. The proposed action would not impact distinct Native American cultural practices or result in disproportionately high and adverse human health or environmental effects on minority communities.

STAFF’S ASSESSMENT

Each technical area section of the SA/DEIS contains a discussion of the project setting, impacts, and where appropriate, mitigation measures and conditions of certification. The SA/DEIS includes the staff’s assessment of:

- the environmental setting of the proposal;
- impacts on public health and safety, and measures proposed to mitigate these impacts;
- environmental impacts, and measures proposed to mitigate these impacts;

- the engineering design of the proposed facility, and engineering measures proposed to ensure the project can be constructed and operated safely and reliably;
- project closure;
- project alternatives;
- compliance of the project with all applicable laws, ordinances, regulations and standards (LORS) during construction and operation;
- environmental justice for minority and low income populations, when appropriate; and
- proposed mitigation measures/conditions of certification.

SUMMARY OF PROJECT RELATED IMPACTS

The analysis of project-related direct, indirect and cumulative impacts within this SA/DEIS shows that staff is able to be conclusive in its assessment of impacts and recommended mitigation for most technical areas while remaining inconclusive for Biological Resources as a result of outstanding information needed. In the technical areas of Land Use, and Visual Resources, the direct and cumulative impacts are significant and unmitigable.

Staff is able to conclude for Biological Resources that for all aspects of the project other than the telecommunications option to install fiber optic cable on the Parker-Blythe #2 transmission line, that direct, indirect and cumulative impacts can be mitigated to less than significant levels, and that the project would conform to LORS. However, staff is unable to determine impacts, appropriate mitigation and whether this option would conform to LORS due to a lack of data associated with the option to establish telecommunications between RSEP and Western's system by installation of a fiber optic cable on the Parker-Blythe #2 Transmission Line. Staff expects to receive this information from the applicant in time to update the record prior to the issuance of the Presiding Member's Proposed Decision and to reflect the updates in the FEIS.

The assessment of Land Use, Recreation and Wilderness reveals that the project would still have the following significant/substantial and unmitigable impacts after implementing the proposed conditions of certification:

- Result in a loss of scenic character when considering both direct and cumulative impacts;
- Contribute substantially to cumulative land use and visual/scenic character impacts;

In addition, RSEP would not be consistent with various Riverside County LORS including various Land Use Element policies and a Multipurpose Open Space Element policy associated with the Riverside County General Plan.

With respect to Visual Resources, the agencies have identified, and staff concludes with respect to CEQA, that the proposed project, after implementing all staff-recommended conditions of certification, would still have significant and unmitigable adverse direct and cumulative visual impacts from several Key Observation Points including:

- Highway SR-62 to background distances of 5 miles or more, due particularly to solar receiver brightness; and
- Portions of the Turtle Mountain Wilderness Area at distances of roughly 5 miles or under due to the combination of mirror-field visibility, mirror-field glare, and solar receiver glare.

Within the local viewshed of Rice Valley and of SR 62 in the project vicinity, the anticipated operational visual impacts of the RSEP in combination with past and foreseeable future projects are considered potentially significant and unmitigable, particularly to motorists on SR 62, and to visitors to the area's many wilderness areas and Joshua Tree National Park. In addition, cumulative night light pollution impacts in the project area could become cumulatively considerable. Within the southern California desert, anticipated cumulative operational impacts of past and foreseeable future region-wide projects are considered cumulatively considerable, potentially significant and unmitigable considering the substantial decline in the overall number and extent of scenically intact, undisturbed desert landscapes, and a substantially more urbanized character in the overall southern California desert landscape. RSEP would not conform with a number of applicable LORS of San Bernardino and Riverside Counties pertaining to preservation of scenic resources and scenic highway view corridors.

The following table summarizes the potential environmental impacts and LORS conformance for each technical section. Following the table is a discussion of the technical area conclusions that are not currently favorable in consideration of:

1. the project's direct, indirect or cumulative impacts would not be mitigated to a less than significant level;
2. the project would not conform to applicable LORS; or
3. staff's determinations are inconclusive at this time due to outstanding data.

Cultural Resources effects are also summarized even though impacts would be mitigated to less than significant. This is in consideration of RSEP's impacts to historic Rice Army Airfield (Rice AAF), the western periphery of Camp Rice and the Desert Training Center Cultural Landscape. Please see the appropriate section of this document for more detailed discussions of the environmental settings, impacts, and proposed mitigation measures and Conditions of Certification for each resource area.

Technical Area	Complies with LORS	Direct & Indirect Impacts Mitigated to Less Than Significant	Cumulative Impacts Mitigated to Less Than Significant

BIOLOGY

Construction of the project would result in the permanent land use conversion of approximately 1,770 acres of habitat to support operation of the solar generator, appurtenant structures, and other project components. This summary provides a general overview of the project impacts to each of the biological resources that are present on the project site, have the potential to be present on the site, or are present off-site and have potential to be indirectly affected by the proposed project. This summary also describes potential mitigation measures that may be employed to avoid or reduce or potentially significant project impacts.

Native Vegetation and Habitat: The RSEP would eliminate or degrade native vegetation and wildlife habitat on the proposed solar generator and interconnector substation sites, and would cause temporary or long-term effects to contiguous habitat north of the solar generator site and along the generator tie-line and Parker-Blythe #2 transmission line alignments. These impacts would affect all plant and wildlife species on the site, including special status species. Construction of the project would result in the permanent land use conversion of approximately 1,770 acres of habitat to support operation of the solar generator, appurtenant structures, and other project components. The majority of this habitat is creosote bush scrub. There are no data available on vegetation types along the Parker-Blythe #2 transmission line. Staff believes that the majority of the alignment crosses creosote bush scrub similar to that on the project site, but it also appears to cross dunes in Rice Valley and numerous washes, some of which may support desert riparian or microphyll wash woodland.

Although construction would not result in the complete loss of vegetation on the solar generator site, staff considers the construction of exclusion fencing (designed to prevent desert tortoise from entering the project site), vegetation mowing, introduction of shade and added moisture from mirror washing, maintenance activity, and risk of invasion by weedy annuals to eliminate or degrade the habitat function of the site for all but the most disturbance-tolerant native species. Disturbance to native vegetation along the transmission line alignments would be limited to access routes, pull sites and tower sites, but mechanical access would cause long-term degradation to affected vegetation and habitat. To minimize project effects on vegetation and habitat, staff has proposed Conditions of Certification **BIO-1** through **BIO-9** (Designated Biologist Selection, Designated Biologist Duties, Biological Monitor Qualifications, Biological Monitor Duties, Designated Biologist and Biological Monitor Authority, Worker Environmental Awareness Program, Biological Resources Mitigation Implementation and Monitoring Plan, Impact Avoidance and Minimization Measures, and Compliance Verification), **BIO-10** (Revegetation and Compensation for Impacts to Native Vegetation), and **BIO-11** (Weed Management Plan). To address specific construction-related impacts to native vegetation and habitat loss, staff has incorporated measures proposed by the applicant and has proposed supplemental measures in Condition of Certification **BIO-16** (Desert Tortoise Habitat Compensation). Staff concludes these measures would reduce impacts of the solar generator facility, generator tie-line, and interconnector substation to vegetation and habitat to a level less than significant. Staff has not determined potential significance of project impacts along the Western Parker-Blythe #2 161-Kv Transmission Line associated with installation of the fiber optic cable telecommunication

option, pending additional biological data.

Rare Plants: One special-status species, chaparral sand verbena, was reported on the RSEP solar generator site and another, Harwood's milk vetch, was reported on the generator tie-line alignment. Other late-season special status species may also occur on the site. There are no available data on special status plant occurrence along the Parker-Blythe #2 transmission line. Staff believes that impacts to chaparral sand verbena would be less than significant under CEQA, and that potentially significant impacts to Harwood's milk vetch can be reduced below a level of significance with the implementation of staff's proposed impact avoidance and minimization measures. These measures are detailed in staff's proposed Conditions of Certification **BIO-1** through **BIO-11**, **BIO-12** (Special-Status Plant Impact Avoidance and Minimization), and **BIO-16**. In addition, **BIO-12** would require additional special-status plant surveys on the Parker-Blythe #2 transmission line and late-season surveys on all project component sites. **BIO-12** provides a strategy to evaluate significance of potential impacts to any special status plants that may be affected by the project, and a series of mitigation measures to reduce those impacts, if any, below a level of significance. Staff concludes that, with mitigation as recommended, impacts of the solar generator site, generator tie-line, and interconnector substation to rare plants would not be significant. Staff has not determined potential significance of project impacts along the Western Parker-Blythe #2 161-Kv Transmission Line associated with installation of the fiber optic cable telecommunication option, pending additional biological data.

Common Wildlife and Nesting Birds: Construction of the RSEP would adversely affect common wildlife and nesting birds due to ground disturbance, operation, and permanent exclusion fencing around the perimeter of the solar generator site. Species unable to disperse to surrounding areas will be confined within the project boundaries by the exclusionary fencing, and would be subject to increased risks of road kill and repeated disturbance from human activities during construction and operation. Off-site effects would include noise, lighting, and other disturbance, as well as potential for introduction and spread of weeds and altered off-site hydrology. Transmission line construction and upgrades would degrade habitat at access points (above) and would cause short-term noise and disturbance impacts to wildlife in the construction area. To reduce project effects on common wildlife and nesting birds, staff has proposed Conditions of Certification **BIO-1** through **BIO-11** (above). Among their other requirements, these conditions would require construction scheduling, pre-construction nesting surveys, and other measures to avoid impacts to nesting birds at all construction sites. In addition, staff has recommended Condition of Certification **BIO-16** (Tortoise Habitat Compensation), which also would serve to compensation habitat for common wildlife species and impacts to nesting birds would be avoided by the application of **BIO-13** (Pre-Construction Nest Surveys and Impact Avoidance Measures for Migratory Birds). Staff concludes that, with mitigation as recommended, impacts of the solar generator site, generator tie-line, and interconnector substation to common wildlife would not be significant. Staff has not determined potential significance of project impacts along the Western Parker-Blythe #2 161-kV Transmission Line associated with installation of the fiber optic cable telecommunication option, pending additional biological data.

Based on research at a smaller project site using similar technology, operation of the project is expected to result in bird collisions with the heliostat mirrors and incineration

at or near focused solar heat at the central tower. Staff cannot quantify the expected impact or assess its significance. Staff has proposed Condition of Certification **BIO-25** (Avian and Bat Protection Plan / Monitoring Operational Impacts Of Solar Collection Facility On Birds), which would require an Avian Protection Plan and a Bird Monitoring Study to monitor the death and injury of birds, and to develop and implement adaptive management measures if those impacts are substantial.

Desert Tortoise: Implementation of the RSEP would result in adverse effects to desert tortoise (federally and State listed as a threatened species). Construction of the proposed project would result in the permanent loss of approximately 1,770 acres of occupied desert tortoise habitat. One desert tortoise was located on the solar generator site during field surveys, and staff estimates that about four tortoises (two adults and one or two juveniles) may live on the site. In addition, about ten tortoise eggs may be expected on the site in a typical year. The transmission line corridors and interconnector substation also are in occupied desert tortoise habitat. To mitigate project impacts to desert tortoises and habitat, staff proposes Conditions of Certification **BIO-1** through **BIO-11** (above), which apply to protection of desert tortoise and other biological resources, and Conditions of Certification **BIO-14** through **BIO-17**, which are specific to desert tortoise. **BIO-14** requires pre-construction clearance surveys and exclusion fencing, to remove desert tortoises from the solar generator site and prevent tortoises from entering the site in the future. **BIO-15** requires implementing a translocation plan in accordance with US Fish and Wildlife Service (USFWS) and California Department of Fish and Game (CDFG) guidelines, to translocate tortoises to suitable off-site habitat and monitor them. **BIO-16** requires acquisition, protection, and enhancement of compensation desert tortoise habitat. Staff's proposed compensation ratio is 1:1 for habitat loss at the solar generator site and 3:1 for habitat loss on the transmission lines and interconnector substation site, so that a total of 1,988 acres of compensation land would be required. In large part, this requirement may be met through dedication and protection of applicant-owned lands contiguous to the solar generator site. These lands, or other compensation lands, would be protected under a conservation easement and managed in perpetuity as desert tortoise habitat. BLM's requirement for mitigation at a 1:1 ratio, which may include funding for BLM to implement desert tortoise habitat enhancement projects on public land, would also serve to satisfy a portion of the compensation mitigation. Staff recommends a security in the amount \$5,213,088.41 to ensure completion of the habitat compensation requirement. This security includes costs to acquire, protect, and manage the compensation lands in perpetuity, as described in the analysis below and in **BIO-16**. Staff's recommended Condition of Certification **BIO-17** requires management actions to prevent any project-related increase in common raven predation on desert tortoises, as well as contribution on a per-acre basis to a region-wide raven management strategy. This suite of mitigation measures was developed by cooperatively by Energy Commission, Western, USFWS, CDFG, and BLM staff. Staff concludes that, with mitigation as recommended, impacts of the solar generator site, generator tie-line, and interconnector substation to desert tortoises would be less than significant pursuant to CEQA and would be fully mitigated as required under the California Endangered Species Act (CESA). Staff has not determined potential significance of project impacts along the Western Parker-Blythe #2 161-Kv Transmission Line associated with installation of the fiber optic cable telecommunication option, pending additional biological data.

Couch's spadefoot: Couch's spadefoot, a toad-like amphibian, is a BLM sensitive species and CDFG Species of Special Concern that breeds in summer rain pools and burrows below ground throughout most of the year. Its potential for occurrence on the solar generator site is low, but suitable habitat may be found on the Parker-Blythe #2 transmission line alignment. Staff's recommended Condition of Certification **BIO-23** (Couch's Spadefoot Surveys and Breeding Habitat Avoidance) would require seasonal breeding habitat surveys and, as applicable, avoidance of breeding pools during construction of any portion of the project. Staff concludes that this measure would reduce potential project impacts below a level of significance.

Mojave Fringe-Toed Lizard: The Mojave fringe-toed lizard is a BLM sensitive species and California Species of Special Concern. Its primary habitat is fine wind-blown (aeolian) sand deposits such as dunes and sandy patches within scrubby vegetation. It is not expected to occur on the solar generator site, but may occur on the generator tie-line alignment or interconnector substation site, and probably occurs on portions of the Parker-Blythe #2 transmission line alignment. Construction impacts to habitat along the transmission lines would be temporary because aeolian habitat is only sparsely vegetated and post-construction habitat recovery would occur naturally in only a short time. Proposed Condition of Certification **BIO-8** requires that generator tie-line construction and fiber optic OPGW installation on the existing Parker-Blythe #2 transmission line shall avoid any aeolian sand habitat wherever feasible, and, avoidance is infeasible, site-specific measures will be developed and implemented. Staff concludes that project impacts to Mojave fringe-toed lizard would not be significant.

Burrowing Owl: Construction of the RSEP would result in direct loss of habitat for the burrowing owl (a BLM sensitive species and a California Species of Special Concern). The applicant estimates up to seven burrowing owls occur on the solar generator site and generator tie line alignment. Staff's proposed Condition of Certification **BIO-19** (Burrowing Owl Impact Avoidance and Compensation Measures) provides measures to avoid take or direct impacts to burrowing owls, and to compensate for habitat loss based on the number of single owls or nesting pairs on the site. Habitat compensation may be "nested" within compensation lands required for desert tortoise habitat compensation (**BIO-16**, above). Staff concludes that project impacts of the solar generator site, generator tie-line, and interconnector substation to burrowing owl would be less than significant with incorporation of recommended mitigation. Staff has not determined potential significance of project impacts along the Western Parker-Blythe #2 161-Kv Transmission Line associated with installation of the fiber optic cable telecommunication option,, pending additional biological data.

Golden Eagle: Golden eagle is a BLM sensitive species, and also is protected under the federal Bald and Golden Eagle Protection Act and is ranked as Fully Protected under the California Fish and Game Code. No suitable nesting habitat is found on the solar generator site or generator tie-line alignment; potential nesting habitat along the existing Parker-Blythe #2 transmission line is unknown. Staff has proposed Conditions of Certification **BIO-18** (Pre- Construction Surveys for Golden Eagles) and **BIO-25** (Avian Protection Plan / Monitoring Operational Impacts Of Solar Collection Facility On Birds), to avoid construction-related disturbance to nesting golden eagles along the transmission line. The generator tie-line could present a new collision or electrocution

threat to golden eagles. Staff's recommended Condition of Certification **BIO-8** requires that transmission lines, fiber optic lines, and all electrical components shall be designed, installed, and maintained in accordance with guidelines and practices as recommended by the Avian Power Line Interaction Committee's publications to reduce the likelihood of large bird electrocutions and collisions. Project construction would eliminate or degrade approximately 1,770 acres of foraging habitat in the region. This loss could interfere with normal behavior, causing golden eagles to forage more widely and therefore spend less time at or near their nests. This effect could be considered "take," pursuant to the Bald and Golden Eagle Protection Act. Staff's recommended Condition of Certification **BIO-16** (above) requires acquisition, protection, and enhancement of compensation desert tortoise habitat; this habitat also would serve as golden eagle foraging habitat. The solar generator may present a collision or incineration hazard to golden eagles. Staff's recommended Condition of Certification **BIO-25** (above) would evaluate that hazard and implement adaptive management measures as determined necessary. Staff concludes that project impacts of the solar generator site, generator tie-line, and interconnector substation to golden eagle would be less than significant with incorporation of recommended mitigation. Staff has not determined potential significance of project impacts along the Western Parker-Blythe #2 161-Kv Transmission Line associated with installation of the fiber optic cable telecommunication option, pending additional biological data.

Burrowing mammals: American badgers and desert kit foxes occur throughout the Project area, and construction activities could crush or entomb these burrowing species. Staff's proposed Condition of Certification **BIO-19**, which requires preconstruction surveys and avoidance measures to protect badgers and kit foxes, would avoid these potential impacts.

State and Federal Jurisdictional Waters: The project would directly or indirectly affect numerous state-jurisdictional desert washes and ephemeral channels on the solar generator site and along transmission line corridors. The US Army Corps of Engineers (ACOE) has determined that streambeds on the solar generator and generator tie-line alignment are not within federal jurisdiction as Waters of the US. Streambeds on the Parker-Blythe #2 transmission line have not been delineated and no ACOE jurisdictional determination has been made. Staff's proposed Condition of Certification **BIO-22** (Streambed Impact Minimization and Compensation Measures) requires the acquisition and protection of offsite streambed habitat at a 1:1 ratio for streambed acreage lost on the solar generator site and generator tie-line alignment, and implementation of Best Management Practices to minimize impacts on the site. Habitat compensation for impacts to state-jurisdictional waters may be "nested" within compensation lands required for desert tortoise habitat compensation (**BIO-16**, above). With implementation of staff's proposed Conditions of Certification **BIO-22** staff concludes that project impacts of the solar generator site, generator tie-line, and interconnector substation to state-jurisdictional waters would be less than significant. In addition, staff recommends Condition of Certification **BIO-28** (Channel Decommissioning and Reclamation Plan), to be implemented upon project termination. ACOE has not indicated whether it holds federal jurisdiction over streambeds potentially impacted along the Western Parker-Blythe #2 161-Kv Transmission Line or whether such impacts would be authorized under a Nationwide General Permit. Staff has not determined potential state jurisdiction or CEQA significance of project impacts along that alignment, pending additional data.

Wildlife Movement: Construction of the proposed RSEP would have the potential to interrupt wildlife movement through the area. The solar generator site could interrupt potential north-south movement at two suitable wildlife crossings over the nearby California Aqueduct, and the project's perimeter fence could direct animals travelling east-west in the area onto State Highway 62 where risk of vehicle strike would be increased. Staff concludes that the potential impacts to north-south movement would be less than significant and that implementation of staff's recommended Condition of Certification **BIO-21** (Fence locations: Logistics, Lay-down Area and Access Road) would reduce potential impacts to east-west movement below a level of significance.

Cumulative Impacts: Staff concludes that without mitigation, the RSEP would contribute to the cumulatively significant loss of regional resources, including the State and federally threatened desert tortoise and other special status species. Impact avoidance and minimization measures described in staff's analysis and included in the conditions of certification would help reduce impacts to these resources. These compensatory measures are necessary to offset project-related losses, and to assure compliance with State and federal laws such as the federal and State Endangered Species Acts. With the implementation of these measures, staff concludes that the solar generator site, generator tie-line, and interconnector substation contributions to cumulative significant impacts to biological resources would not be considerable. Staff has not determined potential cumulative significance of project impacts along the Western Parker-Blythe #2 161-Kv Transmission Line associated with installation of the fiber optic cable telecommunication option, pending additional biological data.

Staff concludes that, with the incorporation of recommended Conditions of Certification **BIO-1** through **BIO-28**, the proposed RSEP solar generator site, generator tie-line, and interconnector substation would be in compliance with applicable Laws, Ordinances, Regulations, and Standards (LORS). Staff has not determined whether the Western Parker-Blythe #2 161-Kv Transmission Line associated with installation of the fiber optic cable telecommunication option, would comply with applicable LORS, pending additional biological data.

CULTURAL RESOURCES

With respect to CEQA, staff concludes that the proposed Rice Solar Energy Project (RSEP) would have significant direct impacts to the features and artifact concentrations associated with the historic Rice Army Airfield (Rice AAF) and the western periphery of Camp Rice (CA-SBA-10526H), as well as potential direct impacts to 23 other eligible or assumed eligible archaeological sites.

Staff finds that the RSEP construction impacts, when combined with impacts from the past, present, and reasonably foreseeable projects, contribute in a small but significant way to the cumulatively considerable adverse impacts to cultural resources at the regional level. Staff recommends the adoption of **CUL-1**, which would reduce RSEP's cumulative impacts to a less than significant level. The program established by this condition of certification would define, document, and nominate the Desert Training Center Cultural Landscape to both the National Register of Historic Places (NRHP) and the California Register of Historical Resources (CRHR). Other solar projects in the

southern desert, including Blythe Solar Power Project, Palen Solar Power Project, and Genesis Solar Energy Project, are also included in this regional effort.

Staff also recommends that the Energy Commission adopt Conditions of Certification **CUL-2** through **CUL-11**, to mitigate RSEP's project-specific cultural resource impacts. These conditions of certification include the following:

- **CUL-2** identifies the positions and qualifications of personnel responsible for implementing and monitoring the Energy Commission cultural resource conditions of certification .
- **CUL-3** specifies the information and project documentation to be supplied by the project owner.
- **CUL-4** requires the preparation and implementation of a Cultural Resources Monitoring and Mitigation Plan (CRMMP), which would structure and govern the implementation of the broader treatment program.
- **CUL-5** would require the preparation of a final Cultural Resources Report (CRR) that would analyze, interpret, and document the results of all field activities and research findings for the RSEP cultural resources management program.
- **CUL-6** would require training of all project personnel to identify, avoid, protect, and provide appropriate notice of potential cultural resources in the project construction area.
- **CUL-7** and **CUL-8** would provide construction monitoring and cultural resources discovery protocols.
- **CUL-9** identifies data recovery protocols for the Rice AAF/Camp Rice.
- **CUL-10** identifies a process for resolving any inconsistencies in impact significance and mitigation requirements, as it would relate to stipulations within an Energy Commission/Western/BLM Memorandum of Agreement (MOA), Section 106 consultation. The MOA may be included in the Western and BLM Final Environmental Impact Statement (FEIS) for the RSEP interconnection and right-of-way application or be released as a separate document. However, the Energy Commission's Staff Assessment (SA) will be published in advance of the FEIS and completion of the MOA. Therefore, there is the possibility that staff's recommended conditions of certification may conflict with the mitigation measures or monitoring protocols identified in this document. Updated information may be needed in the Energy Commission's record to identify or clarify any differences between the Energy Commission conditions of certification and proposed Federal cultural resources mitigation.
- **CUL-11** would require construction of a public use area on the project site as partial mitigation for the impacts to historic and scenic values of the area, also serving to conform with LORS consistent with the requirements of Section 25529 of the Warren-Alquist Act.
- **CUL-12** would ensure previously documented and newly discovered cultural resources within Western's Parker Dam-Blythe Transmission Line No. 2 corridor and Historic Interpretive Area are flagged and avoided during proposed construction.

Implementation of the proposed conditions of certification included in this Cultural Resources section would satisfy the Energy Commission's responsibility to comply with CEQA, ensure consistency with the applicable LORS, and reduce impacts to cultural resources to a less than significant level. The identification of relevant and reasonable mitigation measures also conforms to NEPA requirements for the BLM/Western analysis that can be considered in their Records of Decision (ROD).

LAND USE

The proposed Rice Solar Energy Project would be located on land within the California Desert Conservation Area (CDCA), as amended by the Northern and Eastern Colorado Desert Coordinated Management (NECO) Plan. The project footprint would include approximately 1,410 acres of privately owned property and about 99 acres of "Multiple-Use Class M" (MUC-M) public (federal) lands, managed by the U.S. Bureau of Land Management (BLM), on a 2,560-acre project site. Siting of electrical generation plants on Class M lands requires compliance with federal, state, and local laws and the NEPA environmental review process.

The proposed project would also require BLM approval of an Amendment to the CDCA Plan and issuance of a Right-of-Way (ROW) grant for use of approximately 99 acres: a 10-mile long corridor, 150 feet wide, and a three-square-acre plot for the transmission lines and interconnection substation. The applicant has submitted an initial ROW application with the approximate acreage and alignment, which would be modified to include only the final project footprint prior to issuance.

The proposed project would not:

- Result in the loss or conversion of Farmland or forest land to non-agricultural uses.
- Conflict with or result in a change to any agricultural zoning or existing Williamson Act contracts.
- Conflict with existing zoning for, or cause rezoning of, forest land, timberland, or timberland zoned Timberland Production.
- Directly or indirectly divide an established community.
- Induce substantial population growth in the project area.
- Impact airport operations.

The proposed project would have a less than significant impact on:

- Wilderness and recreation areas.
- Permanent loss of lands within a portion of the proposed project footprint for agriculture, natural resources, and recreation.
- Recreational use of and access to a portion of the proposed project site and surrounding BLM-managed federal lands.
- The historic significance and National Register eligibility of Camp Rice.

- Future land use and development.

The proposed project would have a less than significant impact, with full implementation of the applicable conditions of certification, on:

- Agricultural use (grazing) and access in an established federal rangeland area within the CDCA.
- Consistency with most applicable land use plans, policies, and regulations of an agency with jurisdiction, or that would normally have jurisdiction, over the project.

The proposed project would have the following significant/substantial, unavoidable impacts before considering whether impacts would be mitigated to less than significant with proposed conditions of certification:

- Result in a loss of scenic character when considering both direct and cumulative impacts;
- Result in the loss of a National Register eligible historic resource (Rice Army Airfield).
- Contribute substantially to cumulative land use and visual/scenic character, recreational, biological, and cultural impacts.

The proposed project would still have the following significant/substantial and unmitigable impacts after implementing the proposed conditions of certification:

- Result in a loss of scenic character when considering both direct and cumulative impacts;
- Contribute substantially to cumulative land use and visual/scenic character impacts;

The proposed project would not be consistent with the following laws, ordinances, regulations, and standards, even with implementation of proposed conditions of certification:

- Riverside County General Plan Land Use Element policies: LU 4.3, LU 6.1, LU 8.2, LU 13.1, LU 13.3, LU 20.1, LU 20.2, LU 20.4, LU 30.1
- Riverside County General Plan Multipurpose Open Space Element policy OS 21.1

VISUAL RESOURCES

The agencies have identified, and staff concludes with respect to CEQA, that the proposed project, after implementing all staff-recommended conditions of certification, would still have significant and unavoidable adverse direct and cumulative visual impacts from several Key Observation Points including:

- Highway SR-62 to background distances of 5 miles or more, due particularly to solar receiver brightness; and
- portions of the Turtle Mountain Wilderness Area at distances of roughly 5 miles or under due to the combination of mirror-field visibility, mirror-field glare, and solar receiver glare.

Staff has recommended **Traffic and Transportation** Conditions of Certification **TRANS-6**, Heilostat Positioning Plan, and **TRANS-7**, Power Tower Monitoring Plan, to ensure that potential glare from the project is minimized to the maximum extent possible and does not pose a health and safety risk. However, staff concludes that with these measures, glare from the project, particularly from the solar receiver, would remain a bright, intrusive source of sub-hazardous nuisance glare to viewers on Highway SR 62 and in other locations at distances within a range of 5 miles or more.

Impacts of the Reduced Acreage Alternative, with staff-recommended conditions of certification, would also have significant unavoidable visual impacts. However, the degree and extent of those impacts would be somewhat less than those of the Proposed Project.

Impacts of the North of Desert Center Alternative, with staff-recommended conditions of certification, would also have significant unavoidable visual impacts. Comparison to the proposed project is mixed. Impacts would be less than those of the Proposed Project due to the more developed and visually compromised setting when compared to that of the Proposed Project. However, the number of residents adversely affected would be substantial, and viewers in the easternmost slopes of Joshua Tree National Park could be affected.

Impacts of the State Route 62/Rice Valley Road Generation Tie Line Alternative would have the same significant unavoidable visual impacts as the proposed project, and in addition would substantially increase those impacts by introducing a new line into the immediate visual foreground of State Route 62 (SR-62).

The anticipated visual impacts of the Proposed Project, Reduced Acreage, North of Desert Center and SR 62/Rice Valley Road Generation Tie Line Alternatives, in combination with past and foreseeable future local projects in their local vicinity, and past and foreseeable future region-wide projects in the southern California desert are considered cumulatively considerable and significant.

Along SR 62, there are four proposed solar energy projects including RSEP that would result in a substantial man-made visual intrusion into a majority of the remaining visually intact and scenic portions of SR 62, potentially rendering it ineligible for designation as a State scenic highway. These four projects would affect over 50 miles of the most scenically intact portions of that highway, altering it from a natural, scenically intact desert landscape into one characterized by the strong visual influence of these industrial facilities. In addition, cumulative night light pollution impacts in the project area could become cumulatively considerable. Therefore, within the local viewshed of Rice Valley and of SR 62 in the project vicinity, the anticipated operational visual impacts of the RSEP in combination with past and foreseeable future projects are considered potentially significant and unmitigable, particularly to motorists on SR 62, and to visitors to the area's many wilderness areas and Joshua Tree National Park.

Within the southern California desert, anticipated cumulative operational impacts of past and foreseeable future region-wide projects are considered cumulatively considerable, potentially significant and unmitigable considering the substantial decline in the overall number and extent of scenically intact, undisturbed desert landscapes, and a

substantially more urbanized character in the overall southern California desert landscape.

All action alternatives studied, with staff-recommended conditions of certification, would not conform with a number of applicable local Laws, Ordinances, Regulations and Standards (LORS) of San Bernardino and Riverside Counties pertaining to preservation of scenic resources and scenic highway view corridors, as described under the Compliance With LORS section of this analysis.

NOTEWORTHY PUBLIC BENEFITS

The RSEP, if constructed and operated as proposed, would provide the following benefits to California and its residents:

- RSEP would provide 150 MW of renewable energy power, which will assist in meeting California's Renewable Portfolio Standard, which specifies that retail sellers of electricity serve 20% of their load with renewable energy by 2010. (Pub. Util. Code, § 399.11 et seq.) Gubernatorial Executive Orders increase the requirement to 33% by 2020. (Governor's Executive Order S-14-08.)
- Producing electricity from renewable resources provides a number of significant benefits to California's environment and economy, including improving local air quality and public health, reducing global warming emissions, developing local energy sources and diversifying our energy supply, improving energy security, enhancing economic development and creating jobs. (2009 CEC Integrated Energy Policy Report, page 231.)
- Scientific studies quantify the negative impacts of global climate change to California's and the world's population, food supplies, public health and environment, including flora and fauna of coastal and desert regions. In order to reduce the impact, the State has adopted goals to reduce greenhouse gas (GHG) emissions through, among other things, renewable energy development.
- RSEP would assist the state in meeting its ambitious Greenhouse Gas reduction targets by generating 150 MW of electricity with vastly lower greenhouse gas emissions than existing fossil fuel burning generating facilities.
- By generating electricity without the use of fossil fuels, RSEP would reduce California's dependence on fossil fuels, a diminishing energy source.
- Electricity produced by RSEP would displace fossil-fuel derived power and reduce the need to operate less efficient peaking power plants.
- Energy storage allows RSEP to decouple the process of solar energy collection from that of power generation, allowing the plant to generate steady and uninterrupted power during hours of peak electricity demand, despite cloud cover, and even at night.
- RSEP would provide construction jobs for an average and peak workforce of 280 and 438, respectively, and approximately 47 jobs during operations. Most of those jobs will require highly trained workers.
- With total capital costs for RSEP estimated to be \$750 – 850 million, construction of

RSEP would provide a boost to the economy from the purchase of major equipment, payroll, and supplies.

- The public's access to history associated with Rice AAF, Camp Rice, and the Desert Training Center/California-Arizona Maneuver Area would be significantly enhanced as a result of RSEP.

INTRODUCTION

Allison Shaffer, Liana Reilly and John Kessler

INTRODUCTION

The proposed action evaluated within this Staff Assessment/Draft Environmental Impact Statement (SA/DEIS) is the construction and operation of the Rice Solar Energy Project (RSEP), a proposed solar-thermal generation facility. The RSEP power plant and a portion of the Generation Tie Line would be located on private land, and the remaining portion of the Tie Line would be on public lands managed by the Bureau of Land Management (BLM) in unincorporated eastern Riverside County, California. The interconnection to the electric transmission system would be to Western Area Power Administration's (Western's) Parker-Blythe #2 Transmission Line. The SA/DEIS represents a joint environmental review document developed by the California Energy Commission (Energy Commission), BLM and Western to evaluate potential impacts associated with the proposed action.

When considering a thermal-electric energy project of 50 megawatts or greater for licensing, the Energy Commission is the lead state agency for evaluating environmental impacts of a proposed licensing action under the California Environmental Quality Act (CEQA). The SA, the result of the Energy Commission staff's environmental evaluation process, is functionally equivalent to the preparation of an Environmental Impact Report.

Western, on behalf of the Department of Energy (DOE), is the lead federal agency evaluating environmental impacts of the proposed project under the National Environmental Policy Act (NEPA) as associated with the electrical interconnection to Western's transmission system. The proposed project is located partially on public lands managed by the BLM and would require a right-of-way grant and land use plan amendment to allow project use of those lands. For this reason, BLM is a cooperating agency in evaluating environmental impacts of the proposed project under NEPA, pursuant to an MOU between Western and BLM, and an MOU between DOE's Loan Guarantee Program (LGP) and BLM. The DEIS is the BLM's environmental evaluation of the potential impacts that could result from the authorization of the requested right-of-way and similarly serves as Western's environmental evaluation of the potential impacts that could result from the proposed electrical transmission interconnection. The LGP is also participating with Western in the preparation of this SA/DEIS as the project proponent has applied for a loan guarantee to fund the proposed project.

In August, 2007, the Energy Commission and BLM California Desert District (CDD) entered into a Memorandum of Understanding (MOU) to jointly develop the environmental analysis documentation for solar thermal projects which are under the jurisdiction of both agencies. The purpose of the MOU is to avoid duplication of staff efforts, share staff expertise and information, promote intergovernmental coordination, and facilitate public review. Consistent with the guidelines of the MOU, this document represents the Energy Commission's SA, as well as the BLM's and DOE's DEIS. Following a 90-day public comment period, BLM and Western, on behalf of DOE, will issue a Final EIS.

For Energy Commission purposes, this SA/DEIS is a staff document. It is neither a document of the California Energy Commission Siting Committee, a draft decision by the Siting Committee, nor a Final Decision by the Energy Commission. Similarly, the SA/DEIS does not serve as a decision document that would be used by decision makers when considering approving the right-of-way grant by BLM or the interconnection to Western's transmission system. The SA/DEIS describes and evaluates the following:

- the proposed project;
- the existing environment;
- whether the facilities can be constructed and operated safely and reliably in accordance with applicable laws, ordinances, regulations, and standards (LORS);
- the environmental consequences of the proposed project including potential public health and safety impacts;
- the potential cumulative impacts of the proposed project in conjunction with other existing and known planned developments;
- mitigation measures proposed by the applicant, staff, interested agencies, local organizations, and interveners which may lessen or avoid potential impacts;
- the proposed conditions under which the project should be constructed and operated, if it is certified (known as "conditions of certification"); and
- alternatives to the proposed project.

The analyses contained in this SA/DEIS are based upon information from the: 1) Application for Certification (AFC), 2) responses to data requests, 3) supplementary information from local, state, and federal agencies; interested organizations; and individuals, 4) existing documents and publications, 5) independent research, 6) the Plan of Development submitted by the applicant to the BLM in 2009, and 7) comments at workshops. The SA/DEIS presents conclusions about potential environmental impacts and conformity with LORS, as well as proposed conditions of certification/mitigation measures that apply to the design, construction, operation, and closure of the facility. Each proposed condition of certification/mitigation measure is followed by a proposed means of verification that the condition has been met.

BACKGROUND

SolarReserve, LLC is a Delaware limited liability company with its principal place of business in Santa Monica, California. It has formed limited liability company Rice Solar Energy, LLC (referred to as applicant or SolarReserve hereafter) for the purposes of developing a concentrating solar power generation facility, filing a right-of-way (ROW) application with the BLM for the use of public land, filing for electrical transmission interconnection with Western, and for filing an AFC with the Energy Commission. SolarReserve has executed a Power Purchase Agreement with Pacific Gas and Electric to deliver 150 MW of generating capacity and 450,000 megawatt-hours (MWH) of renewable energy annually to the California market, proposing construction over 30 months beginning in spring 2011 and completing by the fourth quarter of 2013.

Through the limited liability company, the applicant has applied for one ROW grant from the BLM to construct the 161/230 kilovolt (kV) RSEP Generation Tie Line for which a 9-mile section of the overall 10-mile length would pass through BLM land and then interconnect to Western's 161 kV Parker-Blythe Transmission Line #2. In addition, a one-mile long, 12 kV distribution line extension would be constructed from Southern California Edison's distribution line adjacent to State Route 62, which would include a span of less than 200 feet across BLM land. The project would occupy 1,410 acres of private land, use approximately 180 acre feet of water per year, and operate for a term of approximately 30 years.

Solar Reserve has applied to Western to interconnect the proposed Project to Western's transmission system. The new 230-kV transmission line from the solar facility would extend approximately ten miles from the solar facility boundary to a new substation to be constructed adjacent to Western's existing 161 kv Parker-Blythe Transmission Line #2. Additionally, Western would need to replace an overhead ground wire on its existing Parker-Blythe transmission line with a fiber optic ground wire to allow communication from the new plant to the existing system. The substation, to be owned and operated by Western, would be located adjacent to Western's existing Parker-Blythe transmission line. The new substation would be approximately 300 x 400 feet or about three acres. The applicant's request was filed in accordance with Western's Open Access Transmission Service Tariff (Tariff). Western's Tariff provides open access to its transmission system. If there is available capacity in the transmission system, Western provides transmission services through an interconnection.

Additionally, on September 14, 2009, SolarReserve applied to the DOE's LGP for a loan guarantee in response to LGP's July 29, 2009 solicitation announcement (DE-FOA-0000140), pursuant to Title XVII of the Energy Policy Act of 2005 (EPAAct). DOE can comply with the requirements under EPAAct by selecting eligible projects that meet the goals of the Act. SolarReserve has applied to the LGP for a loan guarantee pursuant to Title XVII of the EPAAct. Western, on behalf of DOE, is the lead Federal agency for purposes of NEPA compliance. LGP is participating in the review of this NEPA document to ensure that analyses needed to support its decision-making on whether to provide a loan guarantee to SolarReserve are provided in the SA/DEIS.

The proposed project could help meet the explicit policy goals of the State of California of producing 33% of the state's electricity by renewable sources by 2020, and the Federal goals of producing 10% of the nation's electricity from renewable sources by 2012 and 25% by 2025, and of approving 10,000 MW of non-hydropower renewable energy generated from the public lands by 2015. Authorities include:

- Executive order 13212, dated May 18, 2001, which mandates that agencies act expediently and in a manner consistent with applicable laws to increase the "production and transmission of energy in a safe and environmentally sound manner."
- The Energy Policy Act of 2005 (EPAAct), which requires the Department of the Interior (BLM's parent agency) to approve at least 10,000 MW of non-hydroelectric renewable energy on public lands by 2015. Only a portion of the RSEP Generation Tie Line would be located on public land.

- Governor Schwarzenegger's Executive Order S-14-08 dated November 17, 2008, that raises California's renewable energy goals to 33 percent by 2020 and improves processes for licensing renewable projects.
- Secretarial Order 3285, dated March 11, 2009, which "establishes the development of renewable energy as a priority for the Department of the Interior".

AGENCY AUTHORITIES AND RESPONSIBILITIES

The Energy Commission has the exclusive authority to certify the construction, modification, and operation of thermal electric power plants 50 megawatts (MW) or larger. The Energy Commission certification is in lieu of any permit required by state, regional, or local agencies and by federal agencies to the extent permitted by federal law (Pub. Resources Code, § 25500). The Energy Commission must review power plant AFCs to assess potential environmental impacts including potential impacts to public health and safety, potential measures to mitigate those impacts (Pub. Resources Code, § 25519), and compliance with applicable governmental laws or standards (Pub. Resources Code, § 25523 (d)). The Energy Commission staff's analyses were prepared in accordance with Public Resources Code, section 25500 et seq.; Title 20, California Code of Regulations, section 1701 et seq.; and CEQA (Pub. Resources Code, § 21000 et seq.).

The Bureau of Land Management's authority for the proposed action includes Federal Land Policy and Management Act (FLPMA) of 1976 [43 United States Code (U.S.C.) 1701 et seq.], Section 211 of the Energy Policy Act (EPAAct) of 2005 (119 Stat. 594, 600), and BLM's Solar Energy Development Policy of April 4, 2007. The FLPMA authorizes BLM to issue right-of-way grants for renewable energy projects. Section 211 of the Energy Policy Act of 2005 states that the Secretary of the Interior should seek to have approved a minimum of 10,000 megawatts of non-hydroelectric renewable energy generating capacity on public lands by 2015.

Western must consider interconnection requests to its transmission system in accordance with its Tariff and the FPA. Western satisfies FPA requirements to provide transmission service on a non-discriminatory basis through compliance with its tariff. Under the FPA, FERC has the authority to order Western to allow an interconnection and to require Western to provide transmission service at rates it charges itself and under terms and conditions comparable to those it provides itself. However, Western has discretion whether to allow the interconnection based on its NEPA review.

Title XVII of EPAAct established a Federal loan guarantee program for eligible energy projects that employ innovative technologies. Title XVII of EPAAct authorizes the Secretary of Energy to make loan guarantees for a variety of projects, including those that "avoid, reduce, or sequester air pollutants or anthropogenic emissions of greenhouse gases, and employ new or significantly improved technologies as compared to commercial technologies in service in the United States at the time the guarantee is issued." The Recovery Act amended EPAAct by adding a mandate to promote "job preservation and creation, infrastructure investment, energy efficiency and science, assistance to the unemployed, and State and local fiscal stabilization." The two principal goals of the loan guarantee program are to encourage commercial use in the

United States of new or significantly improved energy-related technologies and to achieve substantial environmental benefits.

PROJECT DESCRIPTION (CASE AND PROPERTY DESCRIPTION)

SolarReserve's concentrating power tower technology consists of a large field of mirrors or heliostats that reflect the sun's energy onto a central receiver positioned on top of a tower. The project features thermal energy storage that allows solar energy to be captured throughout the day and retained in a liquid salt heat storage and transfer medium. When electricity is to be generated, the hot liquid salt is routed to a series of heat exchangers to heat water and produce steam. The steam is used to generate electricity in a conventional steam turbine cycle that would utilize an air-cooled condenser for cooling and to minimize water consumption.

The proposed action is designated by BLM as ROW serial number CACA 051022 as attributable to the generation tie line, a portion of which would be located on BLM land. The site consists of four parcels (Assessor Parcel Numbers 801-070-003, 801-070-004, 801-100-005, 801-100-006) and is located in Sections 24 and 25 of Township 1 South, Range 20 San Bernardino Baseline and Meridian (SBBM), approximately 32 miles west of Parker, Arizona and approximately 40 miles northwest of Blythe, California in Riverside County, California. The nearest community is Vidal Junction, approximately 15 miles northeast. The power plant would occupy 1,410 acres of a larger 2,560-acre project parcel on private land, and within a 3,324-acre privately-owned ownership property located adjacent to, and immediately south of, State Route 62. The portion of the generation tie line proposed for the right-of-way grant to be located on BLM-managed lands comprises approximately 163.64 acres of long-term (life of facility) disturbance, and approximately 218.18 acres of temporary disturbance. The substation facility will comprise of approximately 2.75 acres on public lands and would require a temporary disturbance of approximately 20.66 acres.

Power Plant Long-Term Acreage on Private Lands:

Township 1 South, Range 20 East, San Bernardino Baseline and Meridian

The project site would occupy approximately 1,410 acres on a private land parcel of 3,324 acres within Sections 24 and 25. The RSEP site consists of four parcels with Assessor Parcel Numbers as follows:

- 801-070-003;
- 801-070-004;
- 801-100-005; and
- 801-100-006.

The Linear Facilities would occupy approximately 263 acres.

Sec.22, W1/2, SE1/4.

APPLICANT OBJECTIVES

The applicant's project objectives are set forth below. The fundamental objective is to build a solar project that generates and delivers a minimum of 450,000 megawatt-hours of cost-competitive renewable solar energy annually that will help the State meet its Renewable Portfolio Standard goals for new renewable electric generation. To assist in meeting the requirement for additional generating capacity, SolarReserve has developed solar technology which requires commercial-scale development to demonstrate its technical and commercial viability, and has entered into a power purchase agreement to provide power from renewable sources into the California Independent System Operator (CAISO) system. The applicant's objectives include the following:

1. Generate controllable, predictable renewable power using integral thermal storage technology that:
 - a. Captures solar energy throughout the day, through conditions of varying sunshine and even periods of dense cloud cover;
 - b. Stores thermal energy for electricity production during hours of peak electricity demand, including nighttime hours;
 - c. Generates stable power that enhances grid system stability and helps to facilitate integration of new intermittent renewable resources elsewhere; and
 - d. Avoids the need for support from costly grid resources such as spinning reserves and peaking turbines.
2. Deliver a minimum of 450,000 MWh of cost-competitive renewable power annually;
3. Size the generator output (150 MW) so as to maximize energy deliveries, reliably, during high electric demand hours;
4. Minimize use of public lands by siting the project on private property that is formerly disturbed; and
5. Produce a reliable electricity supply free of carbon emissions to help diversify California's electrical power generation portfolio.

CEQA OBJECTIVES

State Objectives

Senate Bill 1078, passed on 2002, established the California Renewable Portfolio Standard (RPS), which requires utilities to increase their sale of electricity produced by renewable energy sources, including solar facilities, by a minimum of one percent per year with a goal of 20 percent of their total sales by 2017. However, the California Public Utilities Commission, Energy Commission, and the California Power Authority adopted the Energy Action Plan (EAP), which pledged that the agencies would meet an accelerated goal of 20% by the year 2010. As a result, the California Senate passed Senate Bill 107 to be consistent with the EAP, and accelerated the implementation of RPS, requiring utilities to meet the goal of 20% renewable energy generation by 2010. In November 2008, California's Governor instituted Executive Order S-14-08 which establishes an updated RPS goal that all retail sellers of electricity shall serve 33% of their load with renewable energy by 2020. The Mojave Desert has been identified as an area with high potential for solar resource development. The Project would allow California utilities to increase the percentage of renewable resources in their energy portfolio, and aid the utilities in reaching the goals set forth by the RPS.

CEQA guidelines require a clearly written statement of objectives to guide the lead agency in developing a reasonable range of alternatives and aid decision-makers in preparing findings or a statement of overriding considerations. CEQA specifies that the statement of objectives should include the underlying purpose of the project (Section 15126.6(a)). These objectives reflect the applicant's objectives and the BLM's stated purpose and need of the Project and will be considered in the comparison of alternatives, as required under both NEPA and CEQA. The Energy Commission developed the following objectives for the Project:

1. to construct and operate a 150 MW utility-scale solar facility in California capable of interconnecting to the California Independent System Operator (California ISO) Grid through Western's electrical transmission system;
2. to locate the facility in areas of high solarity with ground slope of less than 6 percent; and
3. to contribute to the State of California's renewable energy goals, the National Energy Policy of 2001 (Executive Order 13212), and the Energy Policy Act of 2005 (Public Law 109-58, August 8, 2005) which encourage the development of renewable energy resources.

BLM PURPOSE AND NEED

National Environmental Policy Act (NEPA) guidance published by the Council on Environmental Quality (CEQ) states that environmental impact statements' Purpose and Need section "shall briefly specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action" (40 CFR §1502.13). The following discussion sets forth the purpose of, and need for, the project as required under NEPA.

The purpose of the BLM's proposed action is to approve, approve with modifications, or disapprove a ROW application filed by Rice Solar Energy, LLC (applicant), which is a subsidiary of SolarReserve, LLC to develop the RSEP. The BLM, in conjunction with Western and LGP, will determine and disclose the environmental impacts of the 150 MW RSEP proposal and decide whether granting the requested ROW associated with a portion of the generation tie line and approving the transmission line interconnection respectively are in the public interest. The BLM has determined that the proposed solar project and associated ROW would require an amendment to the CDCA Plan (Plan). The BLM will also consider the amendment of the CDCA Plan to allow for the project.

BLM's purpose and need for the RSEP is to respond to the applicant's application under Title V of the FLPMA (43 USC 1761) for a right-of-way (ROW) grant to construct, operate, maintain, and decommission a generation tie line, a portion of which would be located on public land. These project activities would be associated with development of a concentrated solar electric generation plant along with the associated infrastructure in compliance with FLPMA, BLM Regulations, and other applicable federal laws

The need for the action has its basis in Federal orders and laws that require government agencies to evaluate energy generation projects and facilitate the development of renewable energy sources. The proposed project could help meet the explicit policy goals of the State of California and the Federal goals of producing 10% of the nation's electricity from renewable sources by 2012 and 25% by 2025 and of approving 10,000 MW of non-hydropower renewable energy generated from the public lands by 2015. Authorities include:

- Executive order 13212, dated May 18, 2001, which mandates that agencies act expediently and in a manner consistent with applicable laws to increase the "production and transmission of energy in a safe and environmentally sound manner."
- The Energy Policy Act of 2005 (EPAAct), which requires the Department of the Interior (BLM's parent agency) to approve at least 10,000 MW of renewable energy on public lands by 2015. While the RSEP power plant would not be located on public land, a portion of the generation tie line would be located on public land. Currently, proposed renewable energy projects amounting to about 39,000 MW of electricity are on file with the BLM within the California Desert District; however, it is expected that only a fraction of these will be constructed and operated.
- Secretarial Order 3285A1, dated February 22, 2010, which "establishes the development of renewable energy as a priority for the Department of the Interior".

DOE PURPOSE AND NEED

Western. Western's purpose and need is to approve or deny the interconnection request in accordance with its Tariff and the FPA.

Under the Tariff, Western offers capacity on its transmission system to deliver electricity when capacity is available. The Tariff also contains terms for processing requests for the interconnection of generation facilities to Western's transmission system. The Tariff substantially conforms to Federal Energy Regulatory Commission (FERC) final orders that provide for non-discriminatory transmission system access. Western originally filed

its Tariff with FERC on December 31, 1997, pursuant to FERC Order Nos. 888 and 889. Responding to FERC Order No. 2003, Western submitted revisions regarding certain Tariff terms and included Large Generator Interconnection Procedures (LGIP) and a Large Generator Interconnection Agreement in January 2005. In response to FERC Order No. 2006, Western submitted additional term revisions and incorporated Small Generator Interconnection Procedures and a Small Generator Interconnection Agreement in March 2007. In September 2009, Western submitted yet another set of revisions to address FERC Order No. 890 requirements along with revisions to existing terms.

In reviewing interconnection requests, Western must ensure that existing reliability and service is not degraded. Western's LGIP provides for transmission and system studies to ensure that system reliability and service to existing customers are not adversely affected by new interconnections. These studies also identify system upgrades or additions necessary to accommodate the proposed project and address whether the upgrades/additions are within the project scope.

LGP. The purpose and need of LGP's proposed action is to comply with its mandate under EPAct by selecting eligible projects that meet the goals of the Act. LGP is participating in this NEPA process to assist in determining whether to issue a loan guarantee to SolarReserve to support the proposed project.

LAND USE PLAN CONFORMANCE AND AMENDMENT (BLM)

The principal land use plan affecting this proposed project is the U.S. Bureau of Land Management's (BLM) California Desert Conservation Area (CDCA) Plan of 1980, as amended, and the Northern and Eastern Mojave Desert Colorado Plan (NECO), which amends the CDCA Plan for those areas identified as the northern and eastern Colorado Desert. The CDCA Plan requires that proposed transmission lines (including generation tie lines) located outside of existing designated utility corridors equal to or greater than 161 kV undergo a Plan Amendment process.

Other Agency Plans. For this proposed project, the Energy Commission is the lead agency for CEQA, and an analysis of conformance with applicable Riverside County land use plans is included within the **Land Use, Recreation and Wilderness** section of this SA/DEIS. Land within Riverside County is classified according to the Riverside County General Plan. The General Plan identifies the land area of the proposed RSEP facility as Open Space-Rural (OS-RUR) and is zoned Controlled Development Area (W-2-10) according to the county land use ordinance, a designation that allows use for electric power generation. Therefore, the proposed project conforms to the applicable County General Plan.

Planning Criteria (BLM)

The CDCA Plan planning criteria are the constraints and ground rules that guide and direct the development of the Plan Amendment. They ensure that the Plan Amendment is tailored to the identified issues and that unnecessary data collection and analyses are avoided. They focus on the decisions to be made in the Plan Amendment, and will achieve the following:

“Sites associated with power generation or transmission not identified in the Plan will be considered through the Plan Amendment process.”

Because the proposed facility is not currently identified within the CDCA Plan, an amendment to identify the proposed facility within the Plan is hereby proposed. As specified in Chapter 7, Plan Amendment Process, there are three categories of Plan Amendments, including:

- Category 1, for proposed changes that will not result in significant environmental impact or analysis through an Environmental Impact Statement;
- Category 2, for proposed changes that would require a significant change in the location or extent of a multiple-use class designation; and
- Category 3, to accommodate a request for a specific use or activity that will require analysis beyond the Plan Amendment Decision.

Based on these criteria, approval of the proposed project would require a Category 3 amendment. This section summarizes the procedures necessary to evaluate the proposed Plan Amendment, as well as the procedures required to perform the environmental review of the right-of-way (ROW) application.

Statement of Plan Amendment. The Implementation section of the Energy Production and Utility Corridors Element of the CDCA Plan lists a number of Category 3 amendments that have been approved since adoption of the Plan in 1980. An additional amendment is proposed to be added to this section of the Plan, and would read “Permission granted to construct generation tie line associated with solar energy facility (proposed Rice Solar Energy Project).”

Plan Amendment Process. The Plan Amendment process is outlined in Chapter 7 of the Plan. In analyzing an applicant’s request for amending or changing the Plan, the BLM District Manager, Desert District, will:

1. Determine if the request has been properly submitted and if any law or regulation prohibits granting the requested amendment.
2. Determine if alternative locations within the CDCA are available which would meet the applicant’s needs without requiring a change in the Plan’s classification, or an amendment to any Plan element.
3. Determine the environmental effects of granting and/or implementing the applicant’s request.
4. Consider the economic and social impacts of granting and/or implementing the applicant’s request.
5. Provide opportunities for and consideration of public comment on the proposed amendment, including input from the public and from federal, State, and local government agencies.
6. Evaluate the effect of the proposed amendment on BLM management’s desert-wide

obligation to achieve and maintain a balance between resource use and resource protection.

Decision Criteria for Evaluation of Proposed Plan Amendment. The Decision Criteria to be used for approval or disapproval of the proposed amendment require that the following determinations be made by the BLM Desert District Manager:

1. The proposed amendment is in accordance with applicable laws and regulations;
2. The proposed amendment will provide for the immediate and future management, use, development, and protection of the public lands within the CDCA.

The BLM Desert District Manager will base the rationale for these determinations on the principles of multiple use, sustained yield, and maintenance of environmental quality as required in the Federal Land Policy and Management Act (FLPMA) of 1976.

Decision Criteria for Evaluation of Application. In addition to defining the required analyses and Decision Criteria for Plan Amendments, the Plan also defines the Decision Criteria to be used to evaluate future applications in the Energy Production and Utility Corridors Element of Chapter 3. These Decision Criteria include:

1. Minimize the number of separate rights-of-way by utilizing existing rights-of-way as a basis for planning corridors;
2. Encourage joint-use of corridors for transmission lines, canals, pipelines, and cables;
3. Provide alternative corridors to be considered during processing of applications;
4. Avoid sensitive resources wherever possible;
5. Conform to local plans whenever possible;
6. Consider wilderness values and be consistent with final wilderness recommendations;
7. Complete the delivery systems network;
8. Consider ongoing projects for which decisions have been made; and
9. Consider corridor networks which take into account power needs and alternative fuel resources.

Factors to be Considered. The Plan also states that, in the evaluation of proposed power plants, BLM will use the same factors affecting the public lands and their resources as those used by the Energy Commission. These factors are the environmental information requirements defined in the California Code of Regulations (CCR) Title 20, Appendix B, and include:

- General (Project Overview)
- Cultural Resources

- Land Use
- Noise
- Traffic and Transportation
- Visual Resources
- Socioeconomics
- Air Quality
- Public Health
- Hazardous Materials Handling
- Worker Safety
- Waste Management
- Biological Resources
- Water Resources
- Soils
- Paleontological Resources
- Geological Hazards and Resources
- Transmission System Safety and Nuisance
- Facility Design
- Transmission System Design
- Reliability
- Efficiency

The specific determinations required for the Plan Amendment evaluation are discussed in detail below. This DEIS acts as the mechanism for evaluating both the proposed project application, and the proposed Plan Amendment. The factors specified in CCR Title 20, Appendix B are included within the scope of the analysis presented in the SA/DEIS.

Possible Land Use Plan Amendment and Alternatives

The Applicant has applied for a ROW on public lands in favor of a 161/230 kV transmission line but did not request a CDCA Plan amendment directly. Nonetheless, the BLM has determined that a CDCA Plan amendment would be required if a ROW were granted for the transmission line to support the RSEP. Regardless of whether the proposed project is approved, the BLM could elect to amend the CDCA Plan. Consequently, the following range of outcomes of the BLM's potential CDCA Plan amendment process is as follows:

- PA1 – The CDCA Plan (1980, as amended) would be amended to designate a corridor to allow for the 161/230kV transmission line that would support the RSEP. (This is the proposed land use plan amendment.)
- PA2 – The CDCA Plan (1980, as amended) would not be amended.

PROJECT EVALUATION AND DECISION PROCESS

Energy Commission Process

The Energy Commission's siting regulations require staff to independently review the AFC and assess whether the list of environmental impacts contained is complete and whether additional or more effective mitigation measures are necessary, feasible, and available (Cal. Code Regs., tit. 20, §§ 1742 and 1742.5(a)).

In addition, staff must assess the completeness and adequacy of the measures proposed by the applicant to ensure compliance with health and safety standards and the reliability of power plant operations (Cal. Code Regs., tit. 20, § 1743(b)). Staff is required to develop a compliance plan (coordinated with other agencies) to ensure that applicable laws, ordinances, regulations, and standards are met (Cal. Code Regs., tit. 20, § 1744(b)).

Staff conducts its environmental analysis (Staff Assessment) in accordance with the requirements of the California Environmental Quality Act (CEQA). No additional Environmental Impact Report (EIR) is required because the Energy Commission's site certification program has been certified by the California Resources Agency as meeting all requirements of a certified regulatory program (Pub. Resources Code, § 21080.5 and Cal. Code Regs., tit. 14, § 15251 (j)).

Following a 30-day comment period for the SA/DEIS as it pertains to the Energy Commission's CEQA process (separate from BLM's and Western's 90-day comment period for the Plan Amendment), staff will prepare responses to comments and update the SA/DEIS with an addendum as needed. Staff's impact assessment, including the recommended conditions of certification, is only one piece of evidence that the Siting Committee will consider in reaching a decision on the proposed project and making its recommendation to the full Energy Commission. At the public hearings, all parties will be afforded an opportunity to present evidence and to rebut the testimony of other parties, thereby creating a hearing record on which a decision on the project can be based. The hearing before the Siting Committee also allows all parties to argue their positions on disputed matters, if any, and they provide a forum for the Committee to receive comments from the public and other governmental agencies.

Following the hearings, the Siting Committee's draft recommendation to the full Energy Commission on whether or not to approve the proposed project will be contained in a document entitled the Presiding Members' Proposed Decision (PMPD). Following its publication, the PMPD is circulated for 30 days in order to receive written public comments. At the conclusion of the comment period, the Siting Committee may prepare a revised PMPD. At the close of the comment period for the revised PMPD, the PMPD is submitted to the full Energy Commission for a decision.

BLM and Western Process

Because the Project involves a potential land use plan amendment, the SA/DEIS is required to be available for a 90-day public comment period as it pertains to BLM's NEPA requirements, after which a Final EIS (FEIS) will be issued. BLM and Western will review and develop responses to comments provided by the public and other

agencies during the 90-day public comment period. The responses to the comments and other information identified during this period will be incorporated into a Final EIS (FEIS), which would identify the preferred alternative. These additional comments and responses will also be considered in the PMPD or the revised PMPD, which precedes the Energy Commission's Final Decision. A Notice of Availability (NOA) of the FEIS would be published when the FEIS becomes available for public review. The FEIS would be available for public review for a minimum of 30-days before the BLM and Western issue a Record of Decision (ROD). The decision regarding the ROW grant is in full force and effect upon the issuance of the ROD; however it is also appealable to the Interior Board of Land Appeals upon issuance of the ROD. The FEIS will also contain a proposed decision to amend the BLM Plan. Proposed plan amendment decisions may be protested within 30-days of the proposed decision. BLM cannot make a final decision regarding issuance of a ROW grant or amending the Plan until any Plan protest is resolved.

Under the NEPA process, the significance of the impacts is developed based on the definition of "significantly" provided in NEPA regulations Section 1508.27 (40 C.F.R. § 1508.27). This evaluation includes both the context of the action with respect to the affected resources, as well as the intensity of the effect on those resources. The following are considered in evaluating the intensity:

- Whether the impact is beneficial or adverse;
- The degree to which the proposed action affects public health or safety;
- Unique characteristics of the geographic area, including parks, farmlands, wetlands, wild and scenic rivers, or ecologically critical areas;
- The degree to which the effects are likely to be highly controversial;
- The degree to which the effects are highly uncertain or involve unique or unknown risks;
- The degree to which the action may establish a precedent for future actions;
- Whether the action may be individually insignificant, but cumulatively significant when combined with other actions;
- The degree to which the action may adversely affect significant scientific, cultural, or historical resources;
- The degree to which the action may adversely affect an endangered or threatened species or its habitat; and
- Whether the action threatens a violation of federal, State, or local law or requirements imposed for the protection of the environment.

As outlined in NEPA regulations Section 1502.16 (40 C.F.R. § 1502.16), the analysis also includes a discussion of both direct and indirect effects and their significance, adverse environmental effects which cannot be avoided, whether impacts are short-term or long-term, and any irreversible or irretrievable commitments of resources.

The decisions to be made by the agencies (licensing by the Energy Commission, right-of-way grant by BLM, and approval to interconnect by Western) are independent of each other.

LGP Process

While the SA/DEIS was being developed, LGP also carried out a detailed technical and legal evaluation of the proposed project pursuant to its procedures for loan guarantees set out at 10 CFR Part 609. When the FEIS is completed and made available to the public, LGP will carry out an independent review to ensure that LGP-related comments have been addressed and that the LGP's proposed action is substantially the same as the action described in the EIS. LGP may reach agreement on a conditional commitment for a loan guarantee prior to completion of the SA/DEIS and the approvals by Western and BLM. A condition precedent would be included in the conditional commitment requiring that the NEPA review, Western interconnection approval, and the BLM ROW grant process be completed before LGP closes the loan guarantee transaction.

Following conclusion of the NEPA process, BLM's decision on issuance of the ROW grant, and Western's decision to approve electric transmission interconnection, LGP will issue a Record of Decision (ROD) and proceed to close the loan guarantee transaction provided that the applicant has satisfied all the detailed terms and conditions contained in the conditional commitment and other related documents, and all other contractual, statutory, and regulatory requirements.

Agency Coordination

California Energy Commission

As noted previously, the Energy Commission has the exclusive authority to certify the construction, modification, and operation of thermal electric power plants 50 megawatts (MW) or larger. The Energy Commission certification is in lieu of any permit required by state, regional, or local agencies and by federal agencies to the extent permitted by federal law (Pub. Resources Code, § 25500). The Energy Commission must review power plant AFCs to assess potential environmental impacts including potential impacts to public health and safety, potential measures to mitigate those impacts (Pub. Resources Code, § 25519), and compliance with applicable governmental laws or standards (Pub. Resources Code, § 25523 (d)). The agency's analyses were prepared in accordance with Public Resources Code, section 25500 et seq.; Title 20, California Code of Regulations, section 1701 et seq.; and CEQA (Pub. Resources Code, § 21000 et seq.).

As discussed above, the SA/DEIS for this proposed project was developed as a joint environmental review document, under an MOU between the Energy Commission and BLM California Desert District (CDD) and in cooperation with Western. Throughout the environmental review process, BLM, Western and Energy Commission staff have conducted joint technical analysis, and co-authored the SA/DEIS.

As noted previously, the Energy Commission certification is in lieu of any permit required by state, regional, or local agencies and by federal agencies to the extent

permitted by federal law (Pub. Resources Code, § 25500). However, both the Commission and BLM typically seek comments from and work closely with other regulatory agencies that administer LORS that may be applicable to the proposed project. The following paragraphs describe the agency coordination that has occurred through this joint SA/EIS process.

U.S. Army Corps of Engineers

The U.S. Army Corps of Engineers (USACE) has jurisdiction to protect water quality and wetland resources under Section 404 of the Clean Water Act. Under that authority, USACE reviews proposed projects to determine whether they may impact such resources, and/or be subject to a Section 404 permit. Throughout the FSA/DEIS process, the Energy Commission, BLM, Western and the applicant have provided information to the USACE to assist them in making a determination regarding their jurisdiction and need for a Section 404 permit. The USACE rendered a final opinion on July 27, 2010 concluding that the project does not affect waters of the U.S., and thus does not require such a permit.

National Park Service

The National Park Service manages the Joshua Tree National Park, which is located south of SR 62 roughly 25 miles to the west of the project site. Because of the proximity of Joshua Tree National Park, the Park Service has been invited to participate in scoping meetings and public workshops, and will be provided the opportunity to review and provide comment on the SA/DEIS.

U.S. Fish and Wildlife Service

The U.S. Fish and Wildlife Service (USFWS) has jurisdiction to protect threatened and endangered species under the Endangered Species Act (ESA). Formal consultation with the USFWS under Section 7 of the ESA is required for any federal action that may adversely affect a federally-listed species. The desert tortoise (*Gopherus agassizii*), which occurs in the proposed project area, is a federally-listed threatened species, and therefore formal consultation with the USFWS is required. This consultation was originally initiated in August 2010 through Western's preparation and submittal of a Biological Assessment (BA) which describes the proposed project to the USFWS. This consultation will be reinitiated in October 2010. This consultation has been initiated through the preparation and submittal of a Biological Assessment (BA) which describes the proposed project to the USFWS. Following up to a 135-day review of the BA, the USFWS is expected to issue a Biological Opinion (BO) which will specify mitigation measures which must be implemented for the protection of the desert tortoise.

State Water Resources Control Board/Regional Water Quality Control Board

The Colorado River Basin Regional Water Quality Control Board (RWQCB) has the authority to protect both surface water and groundwater resources at the proposed project location. Throughout the SA/DEIS process, the Energy Commission, BLM, Western and the applicant have invited the RWQCB to participate in public scoping and workshops, and have provided information to assist the agency in evaluating the potential impacts and permitting requirements of the proposed project. The RWQCB has responded by providing comments that have been evaluated and incorporated into

the SA/DEIS analysis. The agency has also made a determination that the proposed project would impact waters of the state, and has specified conditions to satisfy waste discharge requirements. These requirements are included as a recommended Condition of Certification/Mitigation Measure.

California Department of Fish and Game

The California Department of Fish and Game (CDFG) has the authority to protect water resources of the state through regulation of modifications to streambeds, under Section 1602 of the Fish and Game Code. The Energy Commission, BLM, and the applicant have provided information to CDFG to assist in their determination of the impacts to streambeds, and identification of permit and mitigation requirements. The applicant filed a Streambed Alteration Agreement with CDFG on April 30, 2010. The requirements of the Streambed Alteration Agreement will be included as a recommended Condition of Certification/Mitigation Measure.

CDFG also has the authority to regulate potential impacts to species that are protected under the California Endangered Species Act (CESA). On May 5, 2010, the applicant filed an application for authorization for incidental take of the desert tortoise under Section 2081(b) of the CESA. The requirements of the Incidental Take Permit will be included as a recommended Condition of Certification/Mitigation Measure.

Tribal relationships

Western is serving as the lead federal agency for conducting consultation under Section 106 of the Historic Preservation Act and has notified affected Indian Tribes regarding the proposed project, has sought their comments and has invited them to consult on the project on a government-to-government basis.

County of Riverside

County of Riverside reviewed the proposed RSEP, and provided comments as to its LORS conformance that were received on September 21, 2010. While the comments were not received in time to address in the SA/DEIS, the agencies have considered county LORS in preparing the SA/DEIS, and will address the county's comments subsequently to the extent their comments are not already satisfied.

Public Coordination

Both the Energy Commission's CEQA-equivalent process and the BLM's/Western's NEPA process provide opportunities for public participation in the scoping of the environmental analysis, and in the evaluation of the technical analyses and conclusions of that analysis. For the Energy Commission, this outreach program is primarily facilitated by the Public Adviser's Office (PAO). As part of the coordination of the environmental review process required under the Energy Commission/BLM California Desert District MOU and in coordination with Western, the agencies have jointly held public meetings and workshops which accomplish the respective public coordination objectives. This is an ongoing process that to date has involved the following efforts.

Libraries

The AFC was sent to local public libraries in Blythe and Desert Center, California and Parker, Arizona and at public libraries in Fresno, Eureka, San Diego and San Francisco, the California State Library, and the Energy Commission's library in Sacramento.

Outreach Efforts

The PAO's public outreach is an integral part of the Energy Commission's AFC review process. The PAO reviewed information provided by the applicant and also conducted its own outreach efforts to identify and locate local elected and certain appointed officials, as well as "sensitive receptors" (such as schools, community, cultural and health facilities and daycare and senior-care centers, as well as environmental and ethnic organizations). There were no sensitive receptors identified within a six-mile radius of the proposed site for the project.

Notices for workshops and hearings have been and will continue to be distributed to those agencies, individuals, and businesses that are currently on or request to be placed on the project's mailing list. Notices were distributed for the Informational Hearing and Site Visit, which was conducted on January 25, 2010, in Blythe, California.

Coincident with the PAO's outreach efforts, BLM and Western solicited interested members of the public and agencies through the NEPA scoping process. BLM and Western published a Notice of Intent to develop the EIS and amend the CDCA Plan in the Federal Register, Vol. 75, No. 59, pages 15427 - 15429, on March 29, 2010. BLM and Western conducted two Public Scoping meetings for the EIS in accordance with NEPA. The first of these was conducted on March 31, 2010 in Big River and the second was conducted on April 1, 2010 in Palm Desert.

During the process, the Energy Commission, BLM, Western and the applicant coordinated to conduct two workshops. The first was an Issue Resolution workshop which was held in Sacramento, California on March 19, 2010. The second was a Site Visit to Discuss Historical Resources conducted at the RSEP site on June 2, 2010. Both events were announced and made available to the public. The Energy Commission has also continued to accept and consider public comments.

Those agencies and individuals that have provided timely comments concerning the project have been considered in staff's analysis. This SA/DEIS provides agencies and the public with an opportunity to review the Energy Commission staff's analysis of the proposed project. Comments received on this SA/DEIS will be taken into consideration in preparing the subsequent project documents.

Energy Commission regulations require staff to notice, at a minimum, property owners within 1,000 feet of a project and 500 feet of a linear facility under its jurisdiction. This was done for the RSEP project. Staff's ongoing public and agency coordination activities for this project are discussed under the Public and Agency Coordination heading in the **Executive Summary**.

The applicant's AFC, AFC Supplement, Responses to Data Requests, this SA/DEIS, and other project documents are located on the Energy Commission's website at <http://www.energy.ca.gov/sitingcases/ricesolar/index.html>.

Summary of Public and Agency Comments

The BLM/Western and Energy Commission processes include soliciting comments regarding the scope of the analysis from other government agencies, the public, and non-governmental organizations. Issues were identified by reviewing the comment documents received. All of the public comment documents were reviewed and the following section provides a summary of the issues, concerns, and/or questions identified. For this report, the issues have been grouped into one of the three following categories:

- Issues or concerns that could be addressed by effects analysis;
- Issues or concerns that could develop an alternative and/or a better description or qualification of the alternatives;
- Issues or concerns outside the scope of the EIS.

The comments discussed below are paraphrased from the original comment letters. To a minor degree, some level of interpretation was needed to identify the specific concern to be addressed. Similar comments were grouped together and then summarized. Original comment letters may be reviewed upon request at the BLM Palm Springs-South Coast Field Office at 1201 Bird Center Drive, Palm Springs, California, 92262, during normal business hours, from 8:00 am to 4:30 pm.

A. Effects Analysis

Comments in this category will be described in detail in the affected environment section of the EIS or addressed in the effects analysis for each alternative.

Purpose and Need

- Purpose and need should be a clear, objective statement of rationale for the Project
- Project should be discussed in the context of the larger energy market; identify potential purchasers of the power produced; discuss how the Project will assist in meeting its renewable energy portfolio standards and goals

Air Resources and Climate Change

- Greenhouse gas emissions/climate change impacts on plants, wildlife, and habitat
- Discussion of how projected impacts could be exacerbated by climate change
- Cumulative impacts associated with multiple large-scale solar projects and how resources would be affected by climate change
- Quantify and disclose anticipated climate change benefits of solar energy
- Quantify and greenhouse gas emissions from different types of generating facilities and comparing values
- Discussion of trenching/grading/filling and effects on carbon sequestration of the natural desert

- Ambient air conditions; National Ambient Air Quality Standards (NAAQS); criteria pollutant nonattainment areas; potential air quality impacts
- Describe and estimate air emissions, including construction and maintenance activities; specify emission sources by pollutant from mobile sources, stationary sources, and ground disturbance
- Identify need for an Equipment Emissions Mitigation Plan (EEMP)
- Identify need for a Fugitive Dust Control Plan

Water Resources (Surface and Ground water)

- Quantify water usage of Project
- Describe source(s) of water
- Existing groundwater conditions
- Identify potentially-affected groundwater basin
- Basin annual recharge rates
- Water right permitting process and status of water rights within the basin
- Water right permits that contain special conditions
- Cumulative impacts to groundwater quantity and quality, including impacts from other large-scale solar installations
- Types of technology that can minimize water use for solar thermal projects
- Impacts to springs or other open water bodies and biologic resources
- Feasibility of using other sources of water, including wastewater or deepaquifers, as cooling water
- Possibility of recycling water that would be sent to evaporation pond
- Discussion of wet cooling vs. dry cooling systems
- Implementation of conservation measures to reduce water demand
- Subsidence potential
- Effects of climate change on water supply
- Discussion of potential effects of Project discharges, if any, on surface and groundwater quality
- Identify chemical characteristics of pond water and how seepage into groundwater would be prevented
- Identify storm design containment capacity of ponds and how overflow would be managed
- Disposal of wastewater or other fluids into subsurface is subject to requirements of the Underground Injection Control Program; permits may be required
- Determination if Project requires a Section 404 permit under the Clean Water Act (CWA)

- Include a jurisdictional delineation for all waters of the US, including ephemeral drainages
- Description of natural drainage pattern and during Project operations; identify whether any component of Project is within 50 or 100-year floodplain
- Provide information on CWA Section 303(d) impaired waters, if any, and efforts to develop and revise TMDLs

Biological Resources

- If there are threatened or endangered species present, recommend consultation with USFWS and prepare a Biological Opinion under Section 7 of the ESA
- Baseline conditions of habitats and population of covered species
- Description of how avoidance, mitigation, and conservation measures would protect and encourage recovery of covered species and habitats in Project area
- Monitoring, reporting, and adaptive management efforts to ensure species and habitat conservation effectiveness
- Potential impact of construction, installation, operation, and maintenance activities (deep trenching, grading, filling, fencing)
- Potential impacts to native vegetation and/or animal species due to increased shade from heliostats
- Maximize options to protect habitat and minimize habitat loss and fragmentation
- Impacts associated with constructing fences
- Potential impacts on avian species due to collisions with power tower and/or heliostats
- Potential for concentrating solar rays to burn avian species in flight
- If evaporation and/or stormwater ponds would attract wildlife, particularly migratory waterfowl and potential impacts
- Impacts regarding habitat fragmentation, movement corridors, and loss of connectivity
- Impacts due to non-native invasive species
- Inclusion of an invasive plant management plan
- Impacts resulting from vegetation clearance
- Impacts to species due to change in water flow (both surface and groundwater); introduction of pollutants; mortality by vehicle encounters;
- Impacts to species due to alteration of adjacent conservation areas (National Landscape Conservation Lands, Desert Wildlife Management Areas, Areas of Critical Environmental Concern, Wildlife Habitat Management Areas, National Wildlife Refuge System lands, National Park Service Lands, and designated critical habitat

Wildlife Resources (Priority species, special status species)

- Impacts to the following species:
 - Desert tortoise
 - Desert bighorn sheep
 - Migratory birds
 - Eagles, esp. Golden eagle
 - Western burrowing owl
- Activities occurring on lands beyond the boundaries of conservation areas can affect desert tortoise populations
- If Project cannot be designed to avoid impacts to desert tortoise, develop and implement a translocation plan that minimizes take on and adjacent to Project site and associated transmission
- Potential avian mortality from electrocution from transmission lines and power tower
- Recommend use of Avian Protection Plan (APP) Guidelines

Coordination with Tribal Governments

- Describe process and outcome of government to government consultation with tribal governments and how issues, if any, were addressed in selection of proposed alternative
- Address existence of Indian sacred sites in the Project area, including Executive Order 13007 and distinguish it from Section 106 of NHPA
- Identify NRHP eligible sites and development of a Cultural Resource Management Plan

Land Use/Special Designations (ACECs, WAs, WSAs, etc.)

- Discuss how Project would support or conflict with objectives of federal, state, tribal, or local land use plans, policies, and controls

Hazardous Materials

- Direct, indirect, and cumulative impacts of hazardous waste from construction and operation
- Identify hazardous waste types and volumes, and expected storage, disposal, and management plans
- Address applicability of state and federal hazardous waste requirements
- Alternate industrial processes using less toxic materials should be evaluated as mitigation
- Describe concentrated, dewatered solid waste associated with evaporation ponds and whether this waste would be transported offsite for disposal

- Address full product life cycle of components by minimizing impacts during raw material extraction, manufacture heliostats in a zero waste facility, and provide for future heliostat disassembly for material recovery for reuse and recycling

Environmental Justice (minority and low-income communities)

- Evaluation of environmental justice populations within geographic scope of Project and potential for disproportionate adverse impacts to minority and low-income populations; approaches used to foster public participation by these populations; assessment of Project impact on these populations should reflect coordination with those affected populations;

Cumulative Impacts

- Identify current condition of resource as measure of past impacts
- Identify trend in condition of resource as measure of present impacts
- Identify all ongoing, planned, and reasonable foreseeable projects in study area
- Identify future condition of resource based on analysis of impacts from reasonably foreseeable projects or actions
- Assess cumulative impacts contribution of proposed alternatives to long-term health of the resource, and provide specific measurements
- Disclose parties responsible for avoiding, minimizing, and mitigating adverse impacts
- Identify opportunities to avoid and minimize impacts, including working with other entities
- Identify whether the Project is located within a solar energy study area or close proximity
- Consider impacts associated with multiple large-scale solar projects in the desert southwest
- Impacts resulting from additional power supply, including amount of growth and likely location
- Effects of transmission needs of other reasonably foreseeable projects

B. Alternative Development and/or Alternative Design Criteria

Comments in this category will be considered in the development of alternatives or can be addressed through design criteria in the alternative descriptions.

- Alternatives should include discussion of alternative sites, capacities, and generating technologies including different types of solar energy technologies
- Feasibility of using residential and wholesale distributed generation, in conjunction with increased energy efficiency
- Preferred alternative should consider decreasing the capacity, relocating components, and shrinking overall footprint
- Discussion of each alternative's potential to impact air traffic and safety

- Discussion of each alternative's potential to cause adverse aquatic impacts
- Describe current condition of land; whether it is disturbed; and extent it could be used for other purposes
- Describe all waters of the US that could be affected by alternatives, including acreages, channel lengths, habitat types, values, and functions.
- Use of EPA's Renewable Energy Interactive Mapping Tool to explore potential use of disturbed sites in proximity to the Project site that might be utilized
- Pursue siting on disturbed, degraded, and contaminated sites before considering large tracts of undisturbed public lands
- Identify previously disturbed lands in close proximity to existing transmission infrastructure and load centers that could support solar energy projects and reduce impacts to wildlands and species

C. Issues or Concerns Outside the Scope of the EIS

Comments in this category are outside the scope of analysis and will not be addressed in the EIS:

- Commenter states ability to provide easement for transmission line construction
- Commenter states BLM approval process is too complex and lengthy
- Commenter requests reduction of federal controls
- Commenter requests measurement of benefits of Project verses costs
- Commenter questions if BLM could produce power in other ways, such as oil, gas, or nuclear
- Commenter has property interest in area proposed for transmission line

ORGANIZATION OF THE DOCUMENT

The SA/DEIS begins with an Executive Summary, Introduction, Proposed Action Alternative/Project Description, Alternatives, and Cumulative Scenario. The environmental, engineering, and public health and safety analyses of the proposed project are contained in 19 separate chapters. They include the following: Air Quality, Biological Resources, Cultural Resources and Native American Values, Hazardous Materials Management, Land Use, Noise and Vibration, Public Health and Safety, Socioeconomics and Environmental Justice, Soil and Water Resources, Traffic and Transportation, Transmission Line Safety and Nuisance, Visual Resources, Waste Management, Worker Safety and Fire Protection, Geology and Paleontology and Minerals, Facility Design, Power Plant Efficiency, Power Plant Reliability, and Transmission System Engineering. These chapters are followed by the general project conditions, an evaluation of significant unavoidable adverse impacts, the irreversible and irretrievable commitment of resources, and growth inducing effects; summary of public participation efforts; a list of preparers; and references. The organization of the technical section chapters is as follows:

- summary of conclusions
- laws, ordinances, regulations and standards (LORS);

- the regional and site-specific setting;
- project direct and indirect impacts;
- mitigation measures;
- closure and decommissioning impacts and mitigation;
- Reduced Acreage Alternative;
- SR 62/Rice Valley Road Generation Tie Line alternative;
- North of Desert Center alternative;
- no project/no action alternative;
- cumulative impacts;
- noteworthy public benefits;
- mitigation measures/conditions of certification for both construction and operation (as applicable); and
- conclusions and recommendations.

PROPOSED ACTION/PROJECT DESCRIPTION

John Kessler

INTRODUCTION

The applicant for the proposed Rice Solar Energy Project (RSEP) is SolarReserve, LLC, a Delaware limited liability company with its principal place of business in Santa Monica, California. It has formed limited liability company Rice Solar Energy, LLC (referred to as applicant or SolarReserve hereafter) for the purposes of developing a concentrating solar power generation facility. RSEP as proposed requires a right-of-way (ROW) with the U.S. Bureau of Land Management (BLM) for the use of public land associated with the generation tie line, an electrical transmission interconnection with Western Area Power Administration (Western) for transmitting its power, and license certification from the California Energy Commission (Energy Commission). The Applicant will use Solar Reserve's solar thermal technology to develop RSEP which is distinguishable from other concentrated solar power technologies by its use of liquid salt as the heat transfer medium, and its ability to store thermal energy and deliver power when it is most needed.

The applicant filed a right-of-way (ROW) application (CACA 051022) with the BLM on May 12, 2009 as attributable to the generation tie line, a portion of which would be located on BLM land. The applicant filed an Application for Certification (AFC) with the California Energy Commission seeking a license to develop the RSEP on October 21, 2009. On December 2, 2009, the Energy Commission accepted the AFC as data adequate. The analysis contained in the SA/DEIS applies to the proposed project as a whole.

PROJECT LOCATION

The site is located approximately 32 miles west of Parker, Arizona and approximately 40 miles northwest of Blythe, California in Riverside County, California. The nearest community is Vidal Junction, approximately 15 miles northeast. The site is adjacent to State Route 62 (SR-62), which parallels a portion of the Arizona-California Railroad and the Colorado River Aqueduct, near the junction of SR-62 and Blythe-Midland Road, and near the sparse remains of the abandoned town of Rice, California. The power plant would occupy 1,410 acres of a larger 2,560-acre parcel on private land located adjacent to, and immediately south of, SR-62.

The applicant has proposed to locate the RSEP in the Mojave Desert, approximately 32 miles west of Parker, Arizona and approximately 40 miles northwest of Blythe, California in Riverside County, California. The power plant would occupy 1,410 acres of a larger 2,560-acre parcel on private land located adjacent to, and immediately south of, State Route 62 (SR-62). Approximately nine miles of the 10-mile long generation tie line would be located on public land administered by the BLM with the balance on private land. The electrical interconnection would be to Western's Parker-Blythe #2 161 kilovolt (kV) transmission line at a new substation located southeast of the power plant. The nearest community is Vidal Junction, approximately 15 miles northeast. Access to the

site is directly from SR-62 (SR 2009a, Sections 1 and 2). Please see **Project Description Figure 1 – Regional Setting** and **Project Description Figure 2 – Local Setting**.

PROJECT DESCRIPTION

The proposed RSEP would be a concentrating solar thermal power plant development in which most of the power plant area consists of a field of heliostats (elevated mirrors guided by a tracking system) focusing solar energy on a solar receiver heat exchanger located on one centralized power tower. Each heliostat tracks the sun throughout the day and reflects the solar energy to the receiver. The project features thermal energy storage that allows solar energy to be captured throughout the day and retained in a liquid salt heat transfer fluid. When electricity is to be generated, the hot liquid salt is routed to a series of heat exchangers to heat water and produce steam. The steam is used to generate electricity in a conventional steam turbine cycle that would utilize an air-cooled condenser to minimize water consumption.

RSEP is designed to produce electricity at a capacity of 150 megawatts (MW) and annual energy of 450,000 megawatt-hours per year during periods of peak energy demands. The primary components of the 1,410 acre power plant site would include the heliostat field, a 653-foot high central tower and receiver, hot and cold liquid salt storage tanks, a steam-turbine generator and associated equipment, a 20-cell air-cooled condenser, two on-site water wells, three evaporation ponds to capture and evaporate process wastewater, storm water detention basins, an electrical switchyard, and associated administration and maintenance facilities (SR 2009a, Section 2).

The acreages of the project’s land holdings and long term and permanent disturbances associated with the applicant’s final conceptual plans are summarized as follows in **Project Description Table 1**:

**Project Description Table 1
Summary of Project Components and Acreages¹**

Project component	Applicant-owned land	Private land (other)	Public (BLM) land	Total
Total contiguous applicant holdings (six parcels)	3,324 acres	n/a	n/a	3324 acres
Project site (four parcels, to be merged into one)	2,560 acres	n/a	n/a	2560 acres
Solar generation site, including permanent facilities within perimeter fence and Admin. Area	1,410 acres	0	0	1410 acres
Permanent stream channel diversions (outside perimeter fence) ²	35-60 acres			35-60 acres
Long-term construction-phase disturbance (parking, lay-down, logistics)	60 acres	0	0	60 acres
Permanent new access and maintenance road for transmission line (24 ft. wide x 4.6 miles) ³	0		14-16 acres	14-16 acres
Long-term disturbance for new	Negligible		Negligible	Negligible

distribution line (existing line to perimeter of of solar generator site)				
Long-term disturbance for new transmission line towers and pull sites ⁴	10 acres	10 acres	80 acres	100 acres
Permanent disturbance for interconnector substation			3 acres	3 acres
Long-term disturbance for ground line construction on existing Western 161 kV Transmission Line ⁵		Unkn.	Unkn.	127 acres
Total Project disturbance area	1,515-1,540 acres	10 acres +	97-99 acres +	1,749-1,776 acres

1. Data from the Application for Certification (SR 2009a) unless otherwise noted.
2. Staff estimate based on revised RSEP General Arrangement Figure (CH2MHill 2010x).
3. Total generator tie- line right of way = 150 acres Rice Solar Energy Project PLAN OF DEVELOPMENT, September 2009)). Staff estimates road disturbance as 24-foot width x length of road; length is reported as 4.6 miles in SR 2009a, and as 5.4 miles in CH2MHill 2010d.
4. Staff estimates 90 towers and 10 pull sites, each site approximately one acre; approximately 80% of tower and pull sites would be on BLM land.
5. Estimate provided by Western (pers. comm. between S. White and W. Werner).

The proposed project would cause total long term and permanent disturbance of about 1,749 – 1,776 acres, and would utilize about 99 acres of federal land managed by BLM. Please see **Project Description Figure 3 – Visual Simulation from Turtle Mountains Wilderness Area.**

SOLAR POWER PLANT EQUIPMENT AND FACILITIES

HELIOSTATS

Up to 17,500 heliostats would occupy approximately 1,370 acres arranged in concentric circles around the receiver tower. Each heliostat would be configured with a single mirror array hung in the landscape position. Each mirror would be 24 feet high by 28 feet wide, providing a reflective surface of 672 square feet per heliostat (See **Project Description Figure 4 – Heliostats**). Each heliostat has a 12-foot high post or pier-type foundation to support and anchor the unit. The overall height of the heliostats would be about 26 feet when they are facing near horizontally, with about two feet of ground clearance. The heliostat power and control cables would be direct-bury cables in the field up to each individual heliostat unit. Electric power would be distributed from medium voltage switchgear in the power block area via direct-bury cables to step-down transformers located throughout the heliostat field. Low voltage power is then sent via circuit breaker panels and direct-bury cables centrally located in the field to service the individual heliostats. Similarly, command and status signals would be sent to the individual heliostats via direct-bury control cables from the Master Control System (MCS) located in the power block. The command and status signals would be distributed to each unit through Heliostat Field Controllers (HFC's) that would direct the movement of each heliostat to track the movement of the sun (SR 2010b).

The arrangement of the heliostats within the array is optimized to maximize the amount of solar energy that can be collected by the field, and to avoid interference among

heliostats as they track the sun during the day. The heliostats are arranged in arcs encircling the receiver tower extending in concentric rings from the central tower. The receiver tower is offset somewhat to the south of the true center of the heliostat field. Because the plant is situated in the northern hemisphere, this layout optimizes the various sun angles between heliostats and the receiver, given that the sun, on a calendar year basis, remains primarily to the south of the receiver. Heliostats in the northern section of the heliostat array have the highest solar collection efficiency because the sun is predominantly in the southern horizon, and they have the most direct reflection angle to the central tower (most perpendicular to the face of the mirror as it reflects to the central tower). Conversely, heliostats in the southern section of the heliostat array have the lowest solar collection efficiency.

The heliostat spacing will vary through the field with tighter spacing in the center of the field near the power block and central tower. The spacing will gradually become greater as the heliostats are arranged further from the central tower in concentric rows, since the outermost rows will reflect at a flatter angle and require more spacing to avoid shadow effects on each other. The nearest spacing will average 30 feet between heliostats and 27 feet between rows (foundation center to foundation center) at the first two rows nearest the solar tower. The farthest spacing will range from an average of 57 feet between heliostats and 67 feet between rows at the outermost rows on the south side of the solar field, to an average of 60 feet between heliostats and 80 feet between rows at the outermost rows on the north side (CH2MHill 2010a, DR 101).

The heliostats have the ability to rotate 360 degrees around the pedestal and would move in the vertical plane within an approximate range from facing laterally to facing upward. The range of vertical motion can more specifically be defined by referencing two points in that range defined by 0 degrees as facing laterally and 90 degrees as facing upward. If looking at the heliostat from a side view, the full vertical range would vary from a position of 6 degrees upward from facing laterally and would extend to 10 degrees beyond facing perfectly upward (or at a position corresponding to an arc of 100 degrees from facing laterally). The range of motion is as illustrated in **Project Description Figure 4 - Heliostats**. Daily positioning of the heliostats would vary according to operating mode and is described as follows:

1. Night Stow position – During the night, the heliostats would face upward;
2. Morning startup - At dawn, the applicant proposes that the heliostats would be moved from the stowed position to their respective standby position to be readied for sun tracking;
3. Standby position - The standby position is proposed to be relatively close to the tracking position, but instead of reflecting solar energy to the receiver, it would be reflected to one of four target points located at the horizontal center plane elevation of the receiver and approximately 100 feet radially from the receiver surface;
4. Sun tracking - The tracking position that would vary according to the heliostat's location in proximity to the power tower and the sun's position;

5. Evening shutdown – Heliostats would move slowly along predefined paths of motion in groups specified to minimize simultaneous power consumption, and come to rest in the stow position facing upward;
6. Load (power output) reduction – The RSEP thermal energy receiver and storage system can receive all solar energy collected at any time of day, and thus heliostats would not need to be directed away from the receiver to control power output;
7. Reducing solar input to avoid overheating the receiver – In the event the receiver is at risk of overheating, such as related to equipment failure, pre-assigned groups of heliostats would be placed in standby position in order to off-point from the receiver; Should the condition persist for a longer period, the heliostats would be directed to the stow position.
8. Loss of AC station power – The emergency standby generator(s) will automatically start and the entire collector field will begin an emergency defocus sequence where all the heliostats are commanded to point off of the receiver so that all concentrated solar energy is removed within 60 seconds; The applicant has proposed that the heliostats would focus on one of four target points according to the Standby position.
9. Mirror washing - Approximately every two weeks, mirrors would be washed by moving the heliostats into a position between 6 and 45 degrees (CH2MHill 2010a, DRs 150, 151).

SOLAR RECEIVER TOWER AND THERMAL ENERGY COLLECTION AND STORAGE

The solar receiver would be located on the top of a cylindrical concrete tower. The tower structure would be approximately 538 feet tall. The height of the receiver atop the tower would be 100 feet and together, the top of the receiver tower would be 638 feet above the ground surface. A 15-foot high crane would be mounted on top of the receiver to facilitate receiver panel maintenance, making the total height of the receiver tower 653 feet above the ground. The tower would include necessary warning lights to meet Federal Aviation Administration (FAA) regulations. The receiver would be constructed of a series of manifolds and tubes. The cold salt, as stored in a cold liquid salt tank at ground level, would enter the manifold system at approximately 550°F, and would be distributed to the panels of receiver tubes where the solar energy from the heliostats heats the salt to approximately 1,050°F. The heated salt would then flow from the receiver to the hot salt storage tank located at ground level. Before start-up and commissioning of the power plant, the salt mixture of sodium nitrate (NaNO₃) and potassium nitrate (KNO₃) would need to be heated and maintained above the minimum temperature of 450°F to remain in a liquid form.

The thermal energy storage capability allows heat to be stored until required for production of electrical power, allowing power generation to operate independently of solar energy collection. Thermal energy storage provides the ability to extend the power generation period beyond the daylight hours between sunrise and sunset. With the ability for heated salt to be retained in insulated storage tanks, it can be withdrawn and power generated to follow the peak load demands of the electrical grid system which typically includes the afternoon and evening hours after sunset. To produce steam and

generate electricity, the hot salt is pumped through a steam generating system that transfers heat from the salt to water, and supplies superheated steam for use in a conventional Rankine cycle steam turbine-generator. Upon leaving the steam generation system, the salt is returned to the cold tank where it is stored prior to reheating in the solar receiver tower.

The liquid salt system incorporates several “fail safe” features, including gravity drain of the salt loop and steam generation system on loss of grid power in order to avoid solidification should the salt cool down before normal operation can resume. In order to prevent thermal damage to the receiver panels in the event of an interruption in salt flow, an emergency coolant vessel located in the interior of the receiver is filled with low temperature liquid salt pressurized with compressed air to fill the receiver. If the heliostats cannot be directed away from the receiver when salt flow is lost (due to a loss of power), the emergency coolant vessel discharges its contents into the receiver panels to maintain approximately one minute of salt flow. Emergency diesel generators would be installed to provide power for directing the heliostats from the receiver to the Standby Position to prevent overheating of the receiver in the event of a stoppage of salt flow. If power is lost, the diesel generators would have a 10-second start time in order to begin powering the heliostats to the Standby Position in designated groups at a time and in a sequential manner. A 10,000-gallon diesel fuel storage tank would provide on-site storage of diesel adequate to power equipment and building needs for an extended power outage.

(See **Project Description Figure 5 – Project Layout** and **Project Description Figure 6 - Project Elevation**).

POWER BLOCK

When power generation is desired, hot salt is pumped from the hot thermal storage tank into a series of feedwater heaters and steam generation modules to transfer the heat from the hot salt to water and saturated steam, and produce superheated steam. The steam is used in a Rankine cycle reheat steam turbine-generator to produce electricity. Superheated steam is expanded through the high-pressure stages of the turbine, routed back to the steam generation system where it is reheated and then returned to expand through the intermediate and low-pressure turbine sections. The steam turbine drives an attached generator to produce electricity. Waste heat contained in steam exhausted from the turbine is then rejected to the atmosphere through a dry cooling process utilizing an air-cooled condenser. Condensed steam is returned to the steam generation cycle by way of multi-stage condensate and feedwater preheaters and a deaerator.

The RSEP solar power plant would have a power block located slightly south of the center of the solar field. The RSEP solar-thermal plant would include the following equipment and facilities in the power block:

- Hot and cold salt storage tanks;
- solar power tower and receiver;
- steam generation system consisting of an economizer, steam drum, evaporator, and superheater that ultimately converts water to superheated steam for the high-

pressure turbine stage; a reheater of the high-pressure turbine stage exhaust reheats steam for supply to the intermediate and low-pressure turbine stages;

- steam turbine-generator;
- air-cooled condenser for steam condensation;
- auxiliary equipment (feed water heaters, feedwater and condensate pumps, a de-aerator, emergency diesel generator(s), diesel fire pump(s), etc.);
- auxiliary cooling system consisting of an air-cooled and wet surface air cooler for the steam turbine lubricating oil;
- a raw water tank with a 840,000 gallon capacity, to supply water for plant use and fire fighting;
- a demineralized water storage tank;
- water treatment system consisting of two multi-stage reverse osmosis (RO) units and electrodeionization (EDI) equipment; and a
- wastewater treatment system consisting of a reaction chamber, clarifier and filter press to treat the first pass RO reject stream.

Please see **Project Description Figure 7 – General Arrangement of the Power Block Area.**

USE OF FOSSIL FUEL FOR INITIAL SALT CONDITIONING AND EMISSION CONTROLS

Fossil fuels consisting of either propane or compressed natural gas would be used prior to plant startup in two small boilers for the initial melting, heating and conditioning of the salt thermal storage medium. Oxides of Nitrogen (NO_x) emissions from the boilers would be controlled by employing ultra low NO_x burners, and fluid gas recirculation. The RSEP facility may utilize aqueous ammonia (19% NH₃) as an option for emissions control of the salt melting and conditioning equipment during plant commissioning activities. The ammonia would be brought onsite by a licensed contractor in tanker trucks. Liquid ammonia tanker trucks have capacities of up to 11,400 gallons. The capacity of the tanker trucks expected to be used for the RSEP is 7,500 gallons. A maximum of two tanker trucks will be onsite at any time; thus, the maximum amount of ammonia onsite at the RSEP would be 15,000 gallons. The trucks will stay onsite until empty and no permanent ammonia storage tanks will be built for the RSEP.

The salt conditioning process is a one-time event that takes place during plant commissioning, resulting in a closed loop system of liquid salt storage and circulation that will remain heated and contained for the life of the project. The melting and heating process is expected to operate continuously, 24 hours per day and 7 days per week, until the plant's total inventory of 35,000 tons of salt has been melted. The salt commissioning process would take approximately 140 days and is expected to begin in about Month 18 of the construction schedule. The other construction activities and their associated emissions would continue during the salt system commissioning activities.

Fossil fuels will not be needed during RSEP operations except for use in vehicles associated with mirror washing and plant maintenance, with the emergency standby generators for delivering backup station power, and with fire water pumps should station power fail. This equipment would include the latest emission controls as required by California Air Resources Board. Please see the **Air Quality** section for more information on emissions and controls.

WATER SUPPLY AND DISCHARGE

The facilities would require a water source to support operations, including process water consisting of make-up water for the steam system and wash water for the heliostats, and potable water for domestic water needs. Groundwater would be supplied from one of two wells that would be constructed within or in close proximity to the power block. The power block would be connected to the groundwater wells by underground water pipelines. The applicant estimates project water consumption would not exceed a maximum of 180 acre-feet per year (afy), which would primarily be used to provide water for washing heliostats (mirrors) and to maintain proper chemistry of boiler feed water by replacing boiler feed water blow-down. The applicant has estimated that average annual water demands for all project operating needs would be on the order of 100 afy allocated as shown in **Project Description Table 2**.

**Project Description Table 2
Average Daily and Annual Average RSEP Water Demands**

Water Use	Average Daily Use (gpm)¹	Annual Use (AFY)²
<i>Heliostat Mirror Wash</i>	51	31
<i>Steam Cycle Makeup</i>	52	31
<i>Potable Water</i>	5	3
<i>Other uses including wet surface air cooler (WSAC), service water, quench water</i>	62	38
Average Use Total	170	103
<i>Margin for other uses</i>	25	15
Total Plant Consumption	195	118
Maximum Annual Use	--	180
Wastewater Discharge		
<i>Service water</i>	5	--
<i>WSAC blowdown</i>	27	--
<i>Hydrostatic test water</i>	*	--
Average discharge to evap. ponds	32	~20

¹ Gallons per minute

² Acre-feet per year, based on 3,286 hours of operation per year .

¹ Gallons per minute

² Acre-feet per year, based on 3286 hours of operation per year .

* A volume of approximately 6 million gallons will be used during hydrostatic testing. Wastewater discharge facilities shall be operational, and monitoring networks must be installed prior to discharge.

The quality of groundwater would be improved using a treatment system for meeting the requirements of the boiler make-up and mirror wash water. Water treatment equipment would consist of two-pass reverse osmosis membrane filters, and a electrodeionization system. Demineralized water would be stored in a demineralized water storage tank.

FIRE PROTECTION

The fire protection system would be designed to protect personnel and limit property loss and plant downtime in the event of a fire. The primary source of fire protection water would be the 840,000 gallon raw water storage tank to be located in the power block as supplied by the project groundwater well. Approximately 480,000 gallons would be usable for plant process needs and 360,000 gallons would be reserved for fire protection. The project's overall fire water suppression system would be divided into two distinct fire suppression systems. One fire pump set would serve the fire suppression needs within the power block, and the second would serve the needs of the solar receiver tower and administration and shops areas located between SR 62 and the solar field. For both fire water pump systems, an electric jockey pump and electric motor-driven main fire pump would be provided to increase the water pressure to the level required to serve all fire fighting systems. In addition, a backup diesel engine-driven fire pump would be provided for each of the two fire water pump systems to pressurize the fire loop if the power supply to the electric motor-driven main fire pumps fail (SR 2009a, Section 2). The project would not include any specific facilities to address potential wild fires.

RSEP ACCESS DURING CONSTRUCTION AND OPERATIONS

The primary access to RSEP will be from SR 62 into a driveway entering the Administration area. During construction and within the RSEP, there are no planned routes or frequencies for vehicular traffic within the heliostat field. The primary construction activity within the heliostat field will be for installation of the heliostats and includes drilling of a foundation for the heliostat, setting of rebar and anchor bolts within the foundation, pouring of concrete/grout for the foundation, mounting the heliostat pedestal on the foundation, installation of the heliostat panels, installing wiring (power and communication) to each heliostat, creating smooth paths of travel for vehicles, and commissioning of each heliostat. The foundations will be drilled using a large hydraulically driven auger that will be mounted on an excavator, drill rig, or other mobile equipment. Flat bed or other types of trucks will deliver rebar and other supplies. Cranes, forklifts, boom trucks, loaders, or other types of equipment will be used to lift and place the rebar in place. Concrete trucks will deliver concrete to each foundation. Flat bed or other types of trucks will deliver the heliostat parts including the pedestal and panels. Small trenching equipment and backhoes will be used to install cables. Loaders, small dozers, motor graders, water trucks, and compactors will be used to backfill trenches and create smooth roads. Water trucks will apply water for dust suppression and for moisture conditioning of the soils. Pickup trucks and crew trucks will transport men, small tools, and miscellaneous material throughout the heliostat field during the construction and commissioning process.

During RSEP operations, the planned routes of travel have not been determined for operation within the heliostat field. The primary vehicle traffic during operation will be a

water truck for mirror washing. Additional vehicles will include pickup trucks and crew vehicles for maintenance and inspection. Also, mobile cranes or other types of equipment will be used to lift heliostat panels/parts as necessary for maintenance (SR 2009b, Project Description) .

Please see **Project Description Figure 5 – Project Layout** to see the proposed location of the RSEP Main Entrance from SR 62, and the power block and perimeter access roads .

FENCING

The project area would be surrounded by security fence, which would be constructed of galvanized steel chain-link, with barbed wire at the top as required. The security fence would surround the outer perimeter of the power plant, the substation, and the administrative complex. Tortoise barrier fence would also be installed in accordance with the Recommended Specifications for Desert Tortoise Exclusion Fencing (USFWS 2005). The tortoise fence would consist of 1-inch horizontal by two-inch vertical galvanized welded wire. The fence would be installed to a depth of 12 inches, and would extend 22 to 24 inches above the ground surface and integrated with the security fence.

TRANSMISSION SYSTEM INTERCONNECTION AND UPGRADES

The RSEP would deliver power via a 10-mile long 161-kilovolt (kV) transmission generation tie line to a new substation that would be owned and operated by Western. The generation tie line would interconnect to Western's Parker-Blythe #2 transmission line southeast of the RSEP, and the substation would be located adjacent to the transmission line. The new substation would be located on less than three acres on public land. The power plant would have a switchyard with a step-up transformer to increase the 18 kV generator output voltage to 161 kV. The transformer would need to be capable of an output voltage of 230 kV for conversion at such time that Western chooses to operate the Parker-Blythe #2 transmission line at 230 kV. The applicant has proposed that the single circuit generator tie line be supported by 75 to 115-foot high single pole structures. The line would take the most direct and shortest route from the southern limits of the heliostat circle to the new substation, with the first 5.4 miles along a newly built private dirt road connecting to Rice Valley Road, and the remaining 4.6 miles along Rice Valley Road on BLM land to the substation interconnection point (SR2009a, Section 2). Please see **Project Description Figure 1 – Regional Setting** for the locations of the proposed Generation Tie Line and the existing Parker-Blythe #2 transmission line.

The interconnection of the RSEP to Western's Parker-Blythe #2 transmission line would potentially require upgrades to be performed to downstream transmission facilities connected to Western's system associated with Southern California Edison's (SCE's) and Imperial Irrigation District's (IID's) transmission systems. These upgrades are expected to consist of modifications to existing facilities that could include reconductoring, substation switchgear and transformer upgrades and system protection control modifications (CH2MHill 2010s, System Impact Study). Please see the **Transmission System Engineering** section for more information.

RSEP may also have a connection to SCE's distribution system for purposes of supplying power during construction and for backup station power during operations. The 1.1 mile long extension of the 12-kV line would extend SCE's line from a point 175 feet east of the project's eastern parcel boundary in a westward direction along the northern boundary of RSEP paralleling SR 62, and would terminate at RSEP's administration building area. During operations, the electrical service from SCE may serve as a backup for non-operational station power loads. During operations, the station power as primarily fed from RSEP's steam turbine-generator would consume about 10% of RSEP's gross generation as needed to supply plant auxiliaries such as pumps, control systems, lighting, and heating/ventilation/air conditioning (SR 2009a, Section 2).

TELECOMMUNICATIONS FACILITIES

The interconnection of RSEP to Western's transmission system would require telecommunication facilities be installed to provide a protective relay circuit and a supervisory control and data acquisition (SCADA) circuit, together with data and telephone services. The applicant has identified several options for constructing the telecommunication path from RSEP to the new Western interconnection substation, and for communicating to an existing Western substation. To provide for telecommunication pathways from the new RSEP power plant to the new substation, a fiber optic cable would be incorporated with the 10-mile long overhead generation tie line to the new Rice interconnection substation. From the new substation interconnecting the RSEP to Western's system, telecommunications would be established in one of the following manners: 1) replacing one of two existing overhead ground wires on the Parker-Blythe #2 transmission line with a fiber optic core overhead ground wire to either or both of Western's existing Parker and Blythe substations; 2) microwave (radio-frequency) transmission from either RSEP or the new substation to terminate at either Western's Blythe, Headgate Rock, or Black Point substations or to an existing telecommunications site at Cunningham Mountain; or 3) power line carrier/Broadband-over-Power-Line (BPL).

The two optical cable options for the Parker-Blythe #2 transmission line would be integrated with the same poles or towers as would support the generator tie and transmission lines. The BPL option would utilize the electrical conductor of the generator tie and transmission lines. The microwave option could involve an intermediate tower located along the general line of sight of the terminal ends of the microwave path. It is possible that the applicant would run buried fiber optic cable from RSEP to an intermediate tower along the SR 62 ROW if a microwave path selected were near SR 62. If an intermediate tower is needed, it would have a small footprint and could be located to avoid biological and cultural resources (CH2MHill 2010k). (Please see **Project Description Figure 8 – Telecommunications Options**). For more information on the proposed telecommunication facilities, please refer to **Transmission System Engineering Appendix A**.

PROJECT DESIGN AND MANAGEMENT APPROACH

STORMWATER MANAGEMENT APPROACH

The proposed project would utilize a drainage design similar to that of the former Rice Airfield. Runoff received from the north of SR 62 would be diverted outward and away from the site's eastern and western boundaries by constructing the perimeter loop road along the northern half of the heliostat field as a raised feature with a channel on the outward side to direct the flows much like the 1940s-era diversion dike diverted flows from the former Rice Army Airfield. Onsite runoff would only be contained in areas where rainwater could be exposed to contaminants. The solar field runoff would be allowed to discharge freely with minimal concentration. Runoff generated between SR-62 and the site would be conveyed around the site's perimeter by a natural bottom channel (SR 2009a, App. 5.15c).

The existing storm water flow across the proposed project is generally from north to south, across the toe of an alluvial fan originating in the Turtle Mountains. Storm water is conveyed across the site through an extensive network of ephemeral drainages with an average slope of 2%. All drainage in the Rice Valley flows toward the valley's topographic low point, Rice Valley dry playa. During major storm events, the ephemeral washes can flow for periods of a few hours to 24-hours with the possibility of flash floods and mass wasting. The ephemeral drainages have been determined to be non-jurisdictional features by the Army Corps of Engineers under Section 404 of the Clean Water Act (CH2MHill 2010r), but are still considered Waters of the State (SR 2009a). For further discussion on the jurisdictional determination, please refer to the **Biological Resources** section.

The proposed project is sited within a previously modified drainage shed and would be constructed in the same location as the Rice Army Airfield. Directly north of the proposed project site location and north of SR-62 is a railroad currently owned by the California and Arizona Railroad Co. This section of railroad originally owned by Santa Fe Railroad was built no later than the early 1900s. Diversion dikes built to capture runoff from the Turtle Mountains, channel water beneath the railroad tracks. In the late 1930s, the Colorado Aqueduct was constructed immediately up-gradient of the railroad. The aqueduct required its own set of dikes to channel water above the siphoned section of the canal. In its present-day state, these current dikes capture all runoff up-gradient of SR-62 and channel it across the road to the south (SR 2009a).

The Rice Municipal Airport was acquired by the U.S. Army in 1942 and is presumed to have utilized the drainage system currently in place. Water generated up-gradient of the site, in the Turtle Mountains, is conveyed by two diversion dikes around the airfield. These dikes are not currently functioning, due to a lack of maintenance since the airfield was abandoned. After the dikes were breached, it is presumed that the historical natural drainage network re-established itself. The most hydraulically significant drainages on site are those crossing SR-62 adjacent to the project. Two road crossings at SR-62, convey all drainage generated up gradient of the site through or around the project (SR 2009a).

The proposed project is located in Federal Emergency Management Agency (FEMA) Zone D, which is classified as an area with a possible but undetermined flood hazard.

Although a flood hazard analysis has not yet been conducted by FEMA for this area, a Conceptual Drainage Study was completed by the applicant. The proposed project is not within a 100-year floodplain (SR 2009a).

The applicant has proposed that all drainage would collect at the south end of the project in a shallow 30-acre detention facility. This unlined basin would allow for discharge through either infiltration or through a discharge pipe at the lower end of the basin. The function of the discharge pipe would be to maintain the pre-developed discharge rate for the 100-year, 24-hour storm. The project would result in an increase in impervious area from construction of an administration building, a warehouse, power block areas, and a perimeter road. Please see **Project Description Figure 9 – Existing RSEP Site Topography** and **Project Description Figure 10 – Proposed Drainage Plan**.

WASTE MANAGEMENT

Construction activities would generate an estimated 350 cubic yards of non-hazardous solid wastes, consisting of scrap wood, steel, glass, plastic, scrap metal, and paper. Of these items, recyclable materials would be separated and removed to the extent reasonably possible, and transported to recycling facilities. Non-recyclable solid materials (insulation, other plastics, food waste, roofing materials, vinyl flooring and base, carpeting, paint containers, packing materials, etc.) would be disposed of at a Class III landfill (SR 2009a, Table 5.14-1).

Non-hazardous liquid wastes would be generated during construction, and would include equipment washdown water, emission control scrubbing solution purge, storm water runoff and sanitary waste. Storm water runoff would be managed in accordance with appropriate LORS (SR 2009a, Table 5.14-2). Sanitary wastes would be pumped to tanker trucks by licensed contractors for transport to a sanitary wastewater treatment plant. Please see the **SOIL AND WATER RESOURCES** section of this document for more information on the management of project wastewater.

During construction, anticipated hazardous wastes include waste paint, spent construction solvents, waste cleaners, waste oil, oily rags, waste batteries, and spent welding materials. Estimated amounts are 60 empty containers, 7,500 gallons of oils, solvents, and adhesives (every 90 days), and 36 batteries (per year). Empty hazardous material containers would be returned to the vendor or disposed of at a hazardous waste facility; solvents, used oils, paint, oily rags, and adhesives would be recycled or disposed of at a hazardous waste facility; and spent batteries would be transported to a recycling facility (SR 2009a, Table 5.14-1).

During RSEP operations, the proposed project would generate both non-hazardous and hazardous wastes in solid and liquid forms under normal operating conditions. Non-hazardous solid wastes generated during project operations would consist of glass, paper, wood, plastic, cardboard, deactivated equipment and parts, defective or broken electrical materials, empty non-hazardous containers, and other miscellaneous solid wastes. The project would generate approximately 10 cubic yards per year of non-hazardous waste, (the estimate does not include sewage) (SR 2009a, Section 5.14.1.2.2). Such wastes would be recycled to the greatest extent possible, and the

remainder would be removed on a regular basis for disposal in a Class III landfill. Non-hazardous oily rags (one 55-gallon drum per month) would be laundered at an authorized recycle facility. Sanitary wastewater would be treated with an onsite septic system, and sludge would be contained onsite and transported to an off-site disposal facility as needed. Storm water runoff would be managed by diverting oncoming surface runoff around the RSEP site and by allowing on-site runoff to drain as it would naturally from north to south on the RSEP site. The onsite runoff would drain into a 30-acre detention pond where it would infiltrate or be released gradually.

The project proposes to use three five (5)-acre, double-lined evaporation ponds to manage the industrial wastewaters generated by the power block. Each brine pond would have an average design depth of at least six feet to allow for one foot of sludge build up, three feet of operational depth, and two feet of freeboard. The ponds would be constructed and lined as follows:

- a base layer consisting of either a geosynthetic clay liner (GCL) or 2 feet of onsite material with a hydraulic conductivity of less than 1×10^{-6} cm/sec;
- a secondary high density polyethelene (HDPE) liner (minimum of 40 mil);
- a leak detection and removal system comprising a geonet and collection sump; and
- a primary 60 mil high density polyethylene (HDPE) liner at the surface of the ponds.

The wastewater to be discharged into the evaporation ponds is anticipated to be non-hazardous; however, it would contain pollutants which could exceed water quality objectives or affect the beneficial uses of ground water, if released. Therefore, the wastewater would be classified as a “designated waste” and would be regulated by the State and Regional Water Boards. The Colorado River Basin Regional Water Quality Control Board (CRBRWQCB) has jurisdiction over the area where the RSEP would be located. Please see the **SOIL AND WATER RESOURCES** section of this document for more information on storm water and process wastewater disposal.

Hazardous wastes that may be generated during routine project operation include oily absorbent and spent oil filters, and used hydraulic fluid (SR 2009a, p. 5.14-8). In addition, spills and unauthorized releases of hazardous materials or hazardous wastes may generate contaminated soils or cleanup materials that may also require management and disposal as hazardous waste.

PROJECT CONSTRUCTION

The applicant has proposed RSEP construction would begin in the first quarter of 2011, begin startup testing in the first quarter of 2013, and to achieve commercial operation by third quarter of 2013 for an overall 30-month construction period. The applicant expects the peak construction period to occur between months 8 and 20 with a peak construction workforce of up to 438 workers. The applicant proposes to perform construction between 5 AM to 7 PM on weekdays and Saturdays. Construction could occur at times on a 24-hour, seven day-per-week basis to make up schedule deficiencies, to work around extreme mid-day heat or other weather events, or to complete critical construction activities such as when pouring concrete.

FACILITY OPERATION AND MAINTENANCE

Assuming the construction of RSEP were to begin during the first quarter of 2011, the applicant estimates that RSEP construction would be completed and the power plant commercially operational during the third quarter of 2013. The proposed project would be designed for an operational life of 30 years. The RSEP is designed to maximize solar energy collection during daylight hours while enabling the steam turbine-generator to operate during hours of highest system power demands, which generally occur during afternoons and early evenings. The project would be dispatchable, load-following and operated at an annual capacity factor of approximately 35%.

It is anticipated that all the electricity produced by the plant would be sold under contract to one or more power purchasers. The exact operational profile of the plant would be dependent on weather conditions, the power purchaser's economic dispatch decisions and resource scheduling, transmission constraints and other factors. The project would participate in the day-ahead scheduling market controlled by the California Independent System Operator (California ISO) with the power purchaser acting as Scheduling Coordinator for the RSEP. At the time of preparation of this document, the applicant had executed a Power Purchase Agreement with Pacific Gas and Electric that was pending the approval of the California Public Utilities Commission (CPUC).

The applicant anticipates that RSEP operations and maintenance would employ up to 47 full-time employees. Heliostat washing would normally be conducted five days per week using diesel-fueled tank trucks specially fitted with high-pressure washers. The trucks would carry demineralized water and would be driven slowly through the heliostat field, spraying high pressure water onto the heliostat mirrors to remove accumulated dust or foreign matter. The heliostats would be washed about every 2 weeks. Vegetation in the heliostat field would be kept trimmed near ground level, and soil binders and weighting agents would be used to control fugitive dust and minimize dust accumulation on the mirrors as could occur by wind or vehicle traffic.

PROJECT DECOMMISSIONING

Following the operational life of 30 years, the project owner would perform site closure activities to meet federal and state requirements for the rehabilitation and revegetation of the project site after decommissioning. The procedures to be used for project decommissioning and restoration would be in accordance with a Facility Closure Plan. Under this plan, it would be expected that all aboveground structures and facilities would be removed to a depth below grade, and removed offsite for recycling or disposal. Some concrete, piping, and other materials existing below grade may be left in place. Areas that had been graded would be restored to original contours. Shrubs and other plant species would be revegetated.

ALTERNATIVES

Testimony of Suzanne Phinney, D.Env.

SUMMARY OF CONCLUSIONS

In this analysis of the Rice Solar Energy Project, 28 alternatives have been developed and evaluated in addition to the proposed project. These include two modifications of the project at the proposed site, the no project alternative, 12 alternative site locations, a range of solar and renewable energy technologies, generation technologies using different fuels, and conservation/demand-side management.

Of the 28 alternatives, four alternatives were determined to be reasonable by the Bureau of Land Management and Western Area Power Administration (Western) and feasible by the Energy Commission and have the potential to result in reduced impacts in comparison with the proposed project: the Reduced Acreage Alternative, the North of Desert Center Alternative, the SR 62/Rice Valley Road Transmission Line Alternative, and the No Project/No Action Alternative.

CEC Staff have determined that the No Project/No Action Alternative is not superior to the proposed project because it would likely delay development of renewable resources or shift renewable development to other similar areas, and would lead to increased operation of existing power plants that use non-renewable technologies.

The Reduced Acreage Alternative, North of Desert Center Alternative and SR 62/Rice Valley Road Transmission Line Alternative would reduce impacts in comparison to the proposed project. The Reduced Acreage Alternative would incrementally reduce impacts to cultural resources on the historic Rice Army Airfield site and to biological resources. The North of Desert Center Alternative would eliminate all use of the historic Rice Army Airfield, which is also habitat for desert tortoise. Additionally, this alternative would avoid impacts to wildlife movement, alteration of ephemeral streams, and alteration of sand movement. The SR 62/Rice Valley Road Transmission Line Alternative would eliminate the need for a new access road and therefore would reduce impacts to desert habitat. However, these alternatives would not substantially reduce or change the nature of impacts associated with the proposed project, may result in less efficient operations, and could pose feasibility challenges.

The eleven other alternative sites (Cadiz, McCoy, Agricultural Lands, Blythe Mesa, Broadwell Lake, Gabrych, Garlock Road, Manix, Mesquite Lake, Siberia East, and South of Hwy 98) would not substantially reduce impacts and the feasibility of developing projects at these locations is reduced because of size, shape and ownership limitations.

Alternative solar thermal technologies (Stirling dish, solar parabolic trough and linear Fresnel) are also evaluated. As compared with the proposed solar power tower technology, these technologies would not substantially change the severity of visual impacts, biological resources impacts and cultural resource impacts, though land requirements vary among the technologies. Distributed generation solar photovoltaic facilities (i.e., photovoltaic panels placed on surfaces such as rooftops and parking lots) would likewise require extensive square footage or acreage, although they would

minimize the need for undisturbed open space. However, increased deployment of distributed solar photovoltaic technology faces challenges in manufacturing capacity, cost, and policy implementation.

Other generation technologies (wind, geothermal, biomass, tidal, wave, natural gas, and nuclear) are also examined as possible alternatives to the project. These technologies would either be infeasible at the scale of the Rice Solar Energy Project, or they would create their own significant adverse impacts in other locations. For example, a natural gas plant would use substantially less land and avoid cultural and biological resources impacts, but it would contribute to greenhouse gas emissions and would not meet the project's renewable generation objective. Construction of new nuclear power plants is currently prohibited under California law.

Conservation and demand side management programs would likely not meet the state's growing electricity needs that would be served by the Rice Solar Energy Project. In addition, these programs would not provide the renewable energy required to meet the California Renewables Portfolio Standard (RPS) requirements.

Staff's analysis of renewable energy technology options indicates that contributions from each commercially available renewable technology will be needed to meet California's RPS requirements and to achieve the statewide RPS target for 2020 (between 45,000 gigawatt-hours to almost 75,000 gigawatt-hours according to the 2009 Integrated Energy Policy Report). Wave and tidal technologies are not yet commercially available in the United States. Therefore, the combined contribution of the alternatives of wind, distributed solar photovoltaic, geothermal, and biomass is needed to complement rather than substitute for the Rice plant's contribution to meeting statewide RPS requirements.

Alternatives Table 1 lists the alternatives retained for analysis in this Staff Assessment/Draft Environmental Impact Statement (SA/DEIS) and those eliminated, and summarizes the rationale for each conclusion. The locations of all site alternatives are depicted in **Alternatives Figure 1**.

**Alternatives Table 1.
Summary of Alternatives Retained and Eliminated**

Alternative	Rationale for Retention or Elimination
Alternatives Retained for CEQA and NEPA analysis	
Reduced Acreage Alternative	Evaluated in the SA/DEIS because it would reduce impacts to biological and cultural resources.
North of Desert Center Alternative	Evaluated in the SA/DEIS because it would reduce impacts to biological and cultural resources.
SR 62/Rice Valley Road Transmission Line Alternative	Evaluated in the SA/DEIS because it would reduce impacts to desert habitat.
No Project/No Action Alternative	Required under CEQA and NEPA. Do not approve the right-of-way (ROW) grant, do not amend the CDCA Land Use Plan of 1980, as amended, and do not approve interconnection application.

Alternative	Rationale for Retention or Elimination
Alternatives Evaluated but Eliminated from Detailed Analysis	
Cadiz Alternative	Would not substantially reduce impacts of the RSEP project. Location on undisturbed site and significantly longer transmission line would increase the potential for environmental impacts.
McCoy Alternative	Would not substantially reduce impacts of the RSEP project. On BLM rather than private land.
Agriculture Lands Alternative	Inadequate shape and size for RSEP project. Would not substantially reduce impacts.
Blythe Mesa Alternative	Inadequate shape and size for RSEP project. High potential to interfere with Blythe airport.
Broadwell Lake Alternative	Sufficient size with shorter transmission interconnection. However, potentially greater impacts in a number of issue areas (including biological resources, visual resources, and recreation). On BLM rather than private land.
Gabrych Alternative	Inadequate shape for RSEP project. Would not substantially reduce impacts and would have potentially greater impacts in a number of issue areas (including water resources, land use and recreation, visual resources, and noise and vibration).
Garlock Road Alternative	Inadequate shape and size for RSEP project. Would not substantially reduce impacts.
Manix Alternative	Sufficient size. Would not substantially reduce impacts of the RSEP project.
Mesquite Lake Alternative	Site is traversed by many linear features (highways, railroad tracks, canals, and transmission lines) making it too fragmented for the RSEP project.
Siberia East Alternative	Would not substantially reduce impacts of the RSEP project and would potentially have greater impacts in a number of issue areas (including biological and visual resources). On BLM rather than private land.
South of Hwy 98 Alternative	Inadequate shape for RSEP project. Would not substantially reduce impacts and would potentially have greater impacts in a number of issue areas (including recreation and water resources).
Stirling Dish Technology Alternative	Would not substantially reduce impacts of the RSEP project.
Solar Parabolic Trough Alternative	Would not substantially reduce impacts of the RSEP project.
Linear Fresnel Technology Alternative	Would reduce area required but would not eliminate significant impacts of the RSEP Project.
Distributed Solar Technology Alternative	While it will very likely be possible to achieve 250 MW of distributed solar energy over the coming years, the limited numbers of existing facilities make it difficult to conclude with confidence that this much distributed solar will be available within the timeframe required for the RSEP project. Barriers exist related to interconnection with the electric distribution grid. Also, solar PV is one of the components of the renewable energy mix required to meet the California RPS requirements, and additional technologies like solar thermal generation would also be required.

Alternative	Rationale for Retention or Elimination
Wind Energy	A wind project would not reduce impacts in comparison to the RSEP Project. Also, wind is one of the components of the renewable energy mix required to meet the California Renewable Portfolio Standard requirements, so additional technologies like solar thermal generation would also be required.
Geothermal Energy	Transmission infrastructure for multiple geothermal facilities (i.e. 2 to 5 to generate output equivalent to the RSEP) could increase environmental impacts.
Biomass Energy	Most biomass facilities produce only small amounts of electricity (in the range of 3 to 10 MW) and so could not meet the project objectives related to the California RPS. In addition, between 15 and 50 facilities would be needed to achieve 150 MW of generation, creating substantial adverse impacts.
Tidal Energy	Tidal fence technology is commercially available in Europe. However, it has not been demonstrated and proven at the scale that would be required to replace the proposed project, particularly with Pacific tides. Therefore, the development of 150 MW of tidal energy generation capacity within the timeframe required for the RSEP project is considered speculative.
Wave Energy	Unproven technology at the scale that would be required to replace the proposed project; it may also result in substantial adverse environmental impacts.
Natural Gas	Would not attain the objective of generating renewable power meeting California's renewable energy needs.
Coal	Would not attain the objective of generating renewable power meeting California's renewable energy needs and is not a feasible alternative in California.
Nuclear Energy	The permitting of new nuclear facilities in California is not currently allowable by law.
Conservation and Demand-side Management	Conservation and demand-management alone are not sufficient to address all of California's energy needs and would not provide the renewable energy required to meet the California RPS requirements.

INTRODUCTION

Rice Solar Energy, LLC, a wholly owned subsidiary of SolarReserve, LLC, proposes to build the Rice Solar Energy Project (RSEP) on privately owned land in eastern Riverside County. The proposed transmission interconnection with the Western Area Power Administration's Parker-Blythe #2 transmission line would cross both privately owned land and land within the jurisdiction of the BLM. Since the BLM and Western are federal agencies and the California Energy Commission has State authority to license thermal power plants, the RSEP is subject to review under both NEPA and CEQA.

The purpose of this alternatives analysis is to comply with State and Federal environmental laws by providing an analysis of a reasonable range of feasible alternatives which could substantially reduce or avoid any potentially significant adverse impacts of the proposed project. This section summarizes the potentially significant

adverse impacts of the proposed project and analyzes different technologies and alternative sites that may reduce or avoid some or all of those significant adverse impacts.

Four alternatives in addition to the proposed project were determined to be feasible by the BLM/Western and the Energy Commission: the Reduced Acreage Alternative, the North of Desert Center Alternative, the SR 62/Rice Valley Road Transmission Line Alternative, and the No Project/No Action Alternative. These alternatives are analyzed in further detail within each of the technical sections of this document, and are considered for selection as the preferred alternative by the agencies.

This section discusses and analyzes all alternatives eliminated from consideration by the Energy Commission, the BLM and Western.

ALTERNATIVES DEVELOPMENT AND SCREENING PROCESS

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

California Environmental Quality Act Criteria

The *Guidelines for Implementation of the California Environmental Quality Act*, Title 14, California Code of Regulation, section 15126.6(a), provides direction by requiring an evaluation of the comparative merits of “a range of reasonable alternatives to the project, or to the location of the project, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project.” In addition, the analysis must address the No Project Alternative (Cal. Code Regs., tit. 14, § 15126.6(e)).

The range of alternatives is governed by the “rule of reason” which requires consideration only of those alternatives necessary to permit informed decision making and public participation. CEQA states that an environmental document does not have to consider an alternative of which the effect cannot be reasonably ascertained and of which the implementation is remote and speculative (Cal. Code Regs., tit. 14, § 15125(d)(5)).

National Environmental Policy Act Criteria

NEPA requires that the decision-makers and the public be fully informed of the impacts associated with the proposed project. The intent is to make good decisions based on understanding environmental consequences, and to take actions to protect, restore, and enhance the environment.

Alternatives identified must be consistent with BLM and Western’s purpose and need for the action under consideration, which include consideration of the applicant’s objectives (both are defined below). NEPA Sec. 1502.14(a) requires that an Environmental Impact Statement (EIS) rigorously explore and objectively evaluate all reasonable alternatives that are practical or feasible from the technical and economic standpoint and from using common sense, rather than simply desirable from the standpoint of the applicant. (CEQ Forty Questions, No. 1A)

As a general matter, the federal Lead Agency decision makers will ultimately determine the feasibility of each alternative at the time of project approval. It should be noted that NEPA does not limit reasonable alternatives to ones the lead agency can adopt, and the agency should consider wide-reaching alternatives when the issue at hand is a broad one, such as a large-scale energy supply issue. (See *Natural Resources Defense Council, Inc. v. Morton* (D.C. Cir. 1972) 458 F.2d 827, 836 (“*Morton*”).) Further, “[i]n determining the scope of alternatives to be considered, the emphasis is on what is ‘reasonable’ rather than on whether the proponent or applicant likes or is itself capable of carrying out a particular alternative...” (CEQ Forty Questions, No. 2a.)

Consideration of the No Action Alternative is mandated by NEPA. Under the no-action alternative, Western would deny the interconnection request and BLM would not grant a ROW. There would be no plan amendment to the California Desert Conservation Area. As with the CEQA No Project Alternative, this is the scenario that would exist if the proposed project were not constructed.

SCREENING METHODOLOGY

To prepare the alternatives analysis, the following methodology was used:

1. Develop an understanding of the project, identify the basic objectives of the project, and describe its potentially significant adverse impacts.
2. Identify and evaluate technology alternatives to the project such as increased energy efficiency (or demand-side management) and the use of alternative generation technologies (e.g., solar or other renewable or nonrenewable technologies).
3. Identify and evaluate alternative locations for consideration by the Energy Commission.
4. Evaluate potential alternatives to select those qualified for detailed evaluation.
5. Evaluate the impacts of not constructing the project, known as the No Project alternative under CEQA and the No Action alternative under NEPA.

Based on this methodology, each potential alternative was evaluated according the following criteria for its ability to:

- avoid or substantially lessen one or more of the potential significant adverse effects of the project;
- meet most or all of the project objectives;
- be consistent with BLM and Western’s purpose and need.

APPLICANT’S PROJECT OBJECTIVES AND PURPOSE

Five primary objectives are set forth by Rice Solar Energy, LLC (SR 2009a, p. 1-2):

- Provide sustained renewable power using integral thermal storage technology that is controllable and predictable and that can:
- Deliver a minimum of 450,000 MWh of cost-competitive renewable power annually

- Concentrate energy deliveries around high electric demand hours with generator output sized at 150 MW
- Minimize use of public lands by siting the project on previously disturbed private property
- Produce a reliable electricity supply free of carbon emissions to help diversify California's electrical power generation portfolio

Additionally, Rice Solar Energy, LLC states the following purposes of the project:

- Minimize or eliminate the length of transmission interconnections
- Respond to California's on-peak demand for electricity and contributed to the displacement of dirtier, less-efficient fossil fuel generation resources (i.e. peaking turbines) throughout the region
- Support Governor Schwarzenegger's Executive Order S-21-09 to streamline California's renewable energy project approval process and to increase the State's RPS to 33% renewable power by 2020.

PROJECT OBJECTIVES OF THE ENERGY COMMISSION (CEQA)

After considering the objectives set out by the applicant, the Energy Commission has identified the following basic project objectives, which are used to evaluate the viability of alternatives in accordance with CEQA requirements:

- construct and operate a 150 MW utility-scale solar facility in California capable of interconnecting to the California Independent System Operator (California ISO) Grid through Western's electrical transmission system;
- locate the facility in areas of high solarity with ground slope of less than 6%;
- contribute to the State of California's renewable energy goals, the National Energy Policy of 2001, and the Energy Policy Act of 2005 (Public Law 109-58, August 8, 2005) which encourage the development of renewable energy resources; and

PURPOSE AND NEED FOR PROPOSED PROJECT AND PLAN AMENDMENT (BLM AND WESTERN)

Bureau of Land Management. Federal orders and laws require government agencies to evaluate energy generation projects and facilitate the development of renewable energy sources. The Energy Policy Act of 2005 (EPAAct) requires the United States Department of the Interior (DOI), BLM's parent agency, to approve at least 10,000 MW of renewable energy on public lands by 2015. Executive Order 13212, dated May 18, 2001, mandates that agencies expedite their "review of permits or take other actions as necessary to accelerate the completion of such projects, while maintaining safety, public health, and environmental protections" in the "production and transmission of energy in a safe and environmentally sound manner."

Secretarial Order 3283, *Enhancing Renewable Energy Development on the Public Lands*, requires the BLM to ensure that processing and permitting of renewable energy projects complies with the requirements of the National Environmental Policy Act,

Endangered Species Act, National Historic Preservation Act, and all other laws and regulations; improve efficiencies in the processing of renewable energy applications and consistent application of renewable energy policies; and develop Best Management Practices for renewable energy projects on public lands to ensure the most environmentally responsible development of renewable energy.

Secretarial Order 3285, *Renewable Energy Development by the Department of the Interior* requires the BLM to encourage the development of environmentally responsible renewable energy generation. Both of these Secretarial Orders will be considered in responding to the Rice Solar Energy application for the proposed RSEP project.

BLM's purpose and need for the RSEP is to respond to the applicant's application under Title V of the FLPMA (43 USC 1761) for a right-of-way (ROW) grant to construct, operate, maintain, and decommission a generation tie line, a portion of which would be located on public land, and to consider approving an interconnection to Western's electric transmission system respectively. These project activities would be associated with development of a concentrated solar electric generation plant along with the associated infrastructure in compliance with FLPMA, BLM Regulations, Western's regulations and other applicable federal laws. Pursuant to BLM's California Desert Conservation Area (CDCA) Plan (1980, as amended), proposed transmission lines located outside of existing designated utility corridors in excess of 161 kV will be considered through the Plan Amendment process.

Western Area Power Administration. Rice Solar Energy has applied to Western to interconnect the proposed project to Western's transmission system. The new 230-kV transmission line from the solar facility would extend approximately ten miles from the solar facility boundary to a new substation to be constructed adjacent to Western's existing line. The substation, to be owned and operated by Western, would be located adjacent to Western's existing Parker-Blythe #2 transmission line. Western's proposed action is to interconnect the proposed Project to Western's transmission system and to make any necessary modifications to Western facilities to accommodate the interconnection.

Department of Energy. Rice Solar Energy, LLC has also applied to the United States Department of Energy (DOE) for a loan guarantee pursuant to Title XVII of the EAct. Title XVII of EAct authorizes the United States Secretary of Energy to make loan guarantees for a variety of types of projects, including those that "avoid, reduce, or sequester air pollutants or anthropogenic emissions of greenhouse gases, and employ new or significantly improved technologies as compared to commercial technologies in service in the United States at the time the guarantee is issued." The two principal goals of the loan guarantee program are to encourage commercial use in the United States of new or significantly improved energy-related technologies and to achieve substantial environmental benefits. The purpose and need for action by DOE is to comply with their mandate under EAct by selecting eligible projects that meet the goals of the Act.

SUMMARY DESCRIPTION OF THE PROPOSED PROJECT AND PROJECT IMPACTS

The Project Description of the Staff Assessment/Draft Environmental Impact Statement (SA/DEIS) provides a detailed description of the proposed project, and a summary is presented here as context for the alternatives analysis (SR 2009a, Sections 1.0, 2.0, 3.0, 4.0, 5.2, 5.6, 5.15).

The RSEP would be a 150 MW solar thermal facility using concentrating solar power (CSP) technology. A large circular field of mirrors (heliostats) focuses sunlight onto a central receiving tower; up to 17,500 heliostats would occupy 1,410 acres (2.20 square miles). Each 24-foot by 28-foot heliostat would be mounted on a 12-foot tall post. The solar tower and receiver (plus 15-foot crane) would have a total height of 653 feet.

The RSEP would use liquid salt (a mixture of sodium nitrate and potassium nitrate) as the heat transfer fluid. Seventy million pounds (4.4 million gallons) of liquid salt would be stored in insulated hot (1,050° F) and cold (550° F) tanks to retain solar energy. Thermal energy storage allows electric generation beyond sunlight hours and during periods of cloud cover, for an average of 8.4 hours per day. To produce electricity, the salt would circulate through the receiver and steam generation system, where superheated steam is used in a Rankine cycle reheat steam turbine generator. Steam turbine exhaust would be dry-cooled utilizing a 20-cell air-cooled condenser (ACC), which reduces water use. The facility's maximum water consumption would be 180 acre feet per year; daily water use would average 248 gallons per minute. Water would be supplied by two onsite wells and stored in a tank with a capacity of 840,000 gallons.

The project would be located on a 2,560-acre square-shaped parcel within a larger 3,324-acre ownership property in eastern Riverside County's Rice Valley. The ownership property includes portions of Section 24 and 25, Township 1 South, Range 20 East; and all of Sections 19, 20, 29 and 30, Township 1 South, Range 21 East, San Bernardino Base and Meridian. It consists of six Riverside County parcels: APNs 801-042-004, 801-062-012, 801-070-003, 801-070-004, 801-100-005, and 801-100-006. The site is south of State Route 62, 1 mile east of the junction with Blythe-Midland Road. The Arizona-California Railroad and California Aqueduct parallel the north side of the highway. The site was used during WWII as Rice Army Airfield, part of the army's Desert Training Center/California-Arizona Maneuver Area. It was operated privately until abandoned between 1954 and 1958. The nearest active residences are at Vidal Junction, 15 miles to the northeast. Driving distances are 40 miles from Blythe, 65 miles from Needles, 75 miles from Twentynine Palms, and 85 miles from Yuma, Arizona.

The flat and sparsely vegetated Rice Valley is dominated by Sonoran creosote bush scrub habitat. A large wind-blown sand dune system stretches along the southern end of the valley. The valley is bounded by the rugged Turtle Mountains to the north and the Big Maria Mountains to the south. The Arica Mountains are to the west and the West Riverside Mountains to the east, forming a sink with no hydrological connectivity. Rice Valley lacks any major washes. The site is designated open space-rural in the Riverside County General Plan.

The RSEP would interconnect with Western's 161 kV Parker-Blythe #2 transmission line, 10 miles southeast of the site. A new substation (300 feet by 400 feet) would be constructed at the interconnection point. The 10-mile generation tie line that would connect RSEP to Western's Parker-Blythe #2 transmission line would cross private and BLM land; the latter part is adjacent to the Rice Valley Wilderness Area. The gen tie would operate at 161 kV, and could operate at 230 kV with minor transformer modifications when Western converts the Parker-Blythe #2 line to 230 kV. Portions of the transmission line route would be considered by the BLM as Multiple-Use Class M (Moderate Use) per the CDCA. SolarReserve has signed a power purchase agreement with Pacific Gas and Electric (PG&E) for the electricity generated from the RSEP.

The RSEP would not use natural gas and would have no natural gas pipeline connections. Propane would be trucked in for initial salt melting and auxiliary heating.

Environmental impacts for all issue areas would not be significant or would be mitigated to a less than significant level, including impacts to biological resources, cultural resources, and local fire protection. However, the proposed RSEP, with all staff-recommended conditions of certification, would have significant and unavoidable adverse visual impacts.

Impacts of the Reduced Acreage Alternative, with staff-recommended conditions of certification, would also have significant unavoidable visual impacts. However, the degree and extent of those impacts would be somewhat less than those of the Proposed Project. In addition, the smaller footprint would avoid the most active ephemeral washes, and have less impacts to biological resources than the proposed project.

Impacts of the North of Desert Center Alternative, with staff-recommended conditions of certification, would also have significant unavoidable visual impacts. Comparison to the proposed project is mixed. Impacts would be less than those of the Proposed Project due to the alternative's more developed and visually-compromised setting. However, the number of residents adversely affected would be substantial, and viewers in the easternmost slopes of Joshua Tree National Park could be affected. The North of Desert Center is located primarily on fallow land and there would be fewer overall impacts to biological resources as compared to the RSEP site. Although located near an airport, impacts to aviation could be mitigated to less than significant. (The Chuckwalla Valley Raceway privately operates the runway at the Desert Center Airport immediately to the east). However, the alternative site could result in a cumulatively significant impact to local roadway traffic level of service.

Impacts of the SR 62/Rice Valley Road Transmission Line Alternative would have the same significant unavoidable visual impacts as the proposed project, and in addition would substantially increase those impacts by introducing a new transmission line into the immediate visual foreground of SR 62.

The anticipated visual impacts of the Proposed Project, Reduced Acreage, North of Desert Center and SR 62/Rice Valley Road Transmission Line Alternatives, in combination with past and foreseeable future local projects in their local vicinity, and past and foreseeable future region-wide projects in the southern California desert are

considered potentially cumulatively considerable and significant. These action alternatives would fail to conform with a number of applicable local Laws, Ordinances, Regulations and Standards (LORS) of San Bernardino and Riverside Counties pertaining to preservation of scenic resources and scenic highway view corridors.

The alternatives analysis focuses on the consideration of visual resource impacts, along with other environmental and engineering impacts, and the extent to which they could be reduced or eliminated by alternatives to the proposed project.

SUMMARY OF SCOPING AND SCREENING RESULTS

The public scoping comment period allowed the public and regulatory agencies an opportunity to comment on the scope of the SA/EIS, comment on the alternatives considered, and identify issues that should be addressed in the SA/EIS. The discussion below presents the key issues identified from the written and oral comments received during the scoping process on the RSEP project. The specific issues raised during the public scoping process are:

- Alternatives should include discussion of alternative sites, capacities, and generating technologies including different types of solar energy technologies. (Alternative sites addressed under the North of Desert Center Alternative, SR 62/Rice Valley Road Transmission Line Alternative, Applicant's Site Alternatives, and Staff's Site Alternatives; capacities under the Reduced Acreage Alternative; generating technologies under Alternative Renewable Technologies; and solar technologies under Alternative Solar Generation Technologies)
- Feasibility of using residential and wholesale distributed generation, in conjunction with increased energy efficiency. (Distributed solar addressed in Alternative Solar Generation Technologies. Conservation and demand side management addressed in Alternative Methods of Generating or Conserving Electricity, but not discussed in conjunction with distributed solar.)
- Preferred alternative should consider decreasing the capacity, relocating components, and shrinking overall footprint. (The Reduced Acreage Alternative considers a reduced capacity and footprint.)
- Discussion of each alternative's potential to impact air traffic and safety. (Addressed under the Blythe Mesa Alternative, which has a high potential to interfere with air safety and in the Traffic and Transportation section in conjunction with the North of Desert Center Alternative. Other alternative sites are not sited in proximity to active runways.)
- Discussion of each alternative's potential to cause adverse aquatic impacts. (Presence of surface water features and potential to cause aquatic impacts generally discussed for each alternative site in this section. Also discussed in the Soil & Water Resources section for retained alternatives.)
- Description of current condition of land; whether it is disturbed; and extent it could be used for other purposes. (Current condition and uses of land generally discussed for each alternative site in this section. Also discussed in the Land Use section for retained alternatives.)

- Description of all waters of the US that could be affected by alternatives, including acreages, channel lengths, habitat types, values, and functions. (Applicable surface water features discussed under the environmental assessment of each alternative site in this section. Also discussed in the Soil & Water Resources section for retained alternatives.)
- Use of EPA's Renewable Energy Interactive Mapping Tool to explore potential use of disturbed sites in proximity to the Project site that might be utilized. (Comment noted.)
- Pursue siting on disturbed, degraded, and contaminated sites before considering large tracts of undisturbed public lands. (Consistent with Applicant's Project Objectives and Purpose, as listed in this section.)
- Identify previously disturbed lands in close proximity to existing transmission infrastructure and load centers that could support solar energy projects and reduce impacts to wildlands and species. (Project site is on disturbed land; the North of Desert Center alternative is also on disturbed land and near transmission infrastructure.)

Scoping comments are also listed in the **Introduction** section of this SA/DEIS and in the Western/BLM Final Scoping Report.

ALTERNATIVES EVALUATED UNDER NEPA AND CEQA

The requirements for evaluation of alternatives under NEPA and CEQA are described above under the Alternatives Development and Screening Process. This section describes the four alternatives to the proposed project that are retained for analysis: the Reduced Acreage Alternative, the North of Desert Center Alternative, the SR 62/Rice Valley Road Alternative, and the No Project/No Action Alternative. The proposed project and the retained alternatives are evaluated under both NEPA and CEQA in the Environmental Analysis and Engineering Assessment sections of this document.

REDUCED ACREAGE ALTERNATIVE

The Reduced Acreage Alternative would have a 10% smaller heliostat field. It would be located in the same 2,560-acre square-shaped parcel within the larger 3,324-acre ownership property as the proposed project. Although the overall heliostat field distance from the central tower would be reduced, the number of heliostats would remain the same. The heliostat field (plus the evaporation pond and administration areas) would occupy about 1,270 acres instead of the 1,410 acres required for the proposed project. The receiver location would remain the same, with the edges of the field contracting towards the center. The heliostat footprint of the Reduced Acreage Alternative is shown in **Alternatives Figure 2**. The site layout, 653-foot total height of the solar tower and receiver, and transmission interconnection to Western's Parker-Blythe #2 transmission line would be the same as the proposed project. The generation output would be reduced by approximately 2 MW.

Similar to the proposed project, the Reduced Acreage Alternative would transmit power to the grid through the planned Western substation to be located adjacent to Western's Parker-Blythe #2 161 kV transmission line.

The Reduced Acreage Alternative is evaluated in this SA/DEIS because it would eliminate about 140 acres of the proposed project footprint, reducing impacts to ephemeral washes, the loss of land considered habitat for the state- and federally-listed threatened desert tortoise and impacts to the historic Rice airfield. Additionally, the Reduced Acreage Alternative would allow the applicant to contribute clean, renewable energy to help meet the State's energy goals, while minimizing impacts to the desert environment. A limited acreage alternative was suggested in scoping comments.

NORTH OF DESERT CENTER ALTERNATIVE

The North of Desert Center Alternative would be a 150 MW solar thermal facility located on approximately 2,643 acres of land. The site is located along Desert Center Rice Road (State Route 177) east of Kaiser Road, north of Oasis Road, and approximately 1.6 miles north of I-10. The North of Desert Center Alternative is primarily private land with smaller sections of BLM land in the eastern portion of the site. It is largely fallow agricultural land. The existing SCE 161-kV transmission line (from the Blythe-2 substation to the Eagle Mountain-1 substation) that traverses the alternative site would need to be realigned to roughly follow the site boundary. A new 0.125-mile transmission line (along Osborne Ave.) and substation would interconnect to the realigned SCE line at the northeast boundary of the site; a transmission upgrade and a system impact study would likely be required. The boundaries and transmission realignment of the North of Desert Center Alternative are illustrated in **Alternatives Figure 3**.

The North of Desert Center Alternative would utilize concentrated solar power (CSP) technology. A circular field of mirrors (heliostats) surrounding a 653 foot solar tower would occupy 1,410 acres of the site. Approximately 17,500 heliostats would be utilized, each 24-feet by 28-feet and mounted on a 12-foot tall post. The heliostat field, power block, parking areas, administration building, water treatment system, evaporation ponds, and 230-kV switchyard would all be contained within the 1,504-acre fenced project footprint.

The North of Desert Center Alternative is comprised largely of private properties but also includes BLM land in the eastern portion of the site. The site is in the Colorado Desert and meets slope and solarity requirements. The elevation of the site is between 500 and 700 feet above sea level. The majority of the North of Desert Center parcels consist primarily of fallow agriculture land and approximately 84 acres of existing active agriculture in the northwest section. The site would be accessed via Rice Road (SR 177) off the I-10. The alternative would be located just east of the Chuckwalla Valley Raceway, a 400- acre racing facility located at the former Desert Center Airport. Construction of Phases II and III of the Raceway are pending. In addition, the Raceway privately operates the runway at the Desert Center Airport.

The North of Desert Center Alternative is evaluated in this SA/DEIS because it would reduce impacts to cultural resources associated with the historic Rice Army Airfield. This alternative would also reduce biological resource impacts and would avoid impacts to wildlife movement, alteration of ephemeral streams, and alteration of sand movement associated with the proposed project. The North of Desert Center Alternative would allow the applicant to contribute clean, renewable energy to help meet the State's energy goals, while minimizing impacts to the desert environment.

Under the North of Desert Center Alternative, approval by the agencies would require the applicant to submit new applications to the Energy Commission, Western and BLM, which would then be reviewed and a new environmental document prepared.

SR 62/RICE VALLEY ROAD TRANSMISSION LINE ALTERNATIVE

The SR 62/Rice Valley Road Transmission Line Alternative would interconnect to Western's 161-kV/230-kV Parker-Blythe #2 transmission line at the same location as the proposed project transmission line. This alternative transmission line would exit the power block directly to the east and follow a proposed access road within the heliostat field. The gen tie would then turn north inside the RSEP property boundary and run along the RSEP's circular perimeter road to the north and northwest. At the north end of the heliostat field, the route would traverse the construction laydown area, on previously disturbed land, over a distance of approximately 500 feet to the southern side of State Route 62. The route would follow State Route 62 approximately 3.8 miles east to the junction of Rice Valley Road. It would then trend south to follow the unpaved Rice Valley Road for 4.1 miles to its juncture with the applicant's proposed new transmission line alignment and continue southeast for 5.4 miles along the proposed alignment to Western's Parker-Blythe #2 transmission line. The SR 62/Rice Valley Road Transmission Line Alternative route is illustrated in **Alternatives Figure 4**.

The SR 62/Rice Valley Road Transmission Line Alternative is evaluated in this SA/DEIS because it would avoid the permanent loss of 13.4 acres of foraging and cover habitat for plant and animal species, including desert tortoise. It would also avoid the creation of a new 4.6 mile vehicle access route between the proposed solar facility and the proposed junction of the new transmission line access road with the existing Rice Valley road.

NO PROJECT/NO ACTION ALTERNATIVE

CEQA No Project Alternative

The No Project Alternative under CEQA defines the scenario that would exist if the proposed RSEP project were not constructed. The CEQA Guidelines state that "the purpose of describing and analyzing a 'no project' alternative is to allow decision makers to compare the impacts of approving the proposed project with the impacts of not approving the proposed project" (Cal. Code Regs., tit. 14 § 15126.6(i)). The No Project analysis in this SA/DEIS considers existing conditions and "what would be reasonably expected to occur in the foreseeable future if the project were not approved..." (Cal. Code Regs, tit. 14 § 15126.6(e)(2)).

If the No Project Alternative were selected, the construction and operational impacts of the RSEP project would not occur. There would be no grading of the site, no loss of resources or disturbance of approximately 2,560 acres (for the square-shaped parcel) of desert habitat, and no installation of power generation and transmission equipment. The No Project Alternative would also eliminate contributions to cumulative impacts on a number of resources and environmental parameters in eastern Riverside County and in the Mojave Desert as a whole.

In the absence of the RSEP project, however, other power plants, both renewable and non-renewable, may have to be constructed to serve the demand for electricity and to meet RPS requirements. The impacts of these other facilities may be similar to those of the proposed project because these technologies could require large amounts of land like that required for the RSEP project. They may be located on desert habitat that has not been previously disturbed, and may be on public rather than privately-owned land. The No Project/No Action Alternative may also lead to siting of other non-solar renewable technologies to help achieve the California RPS.

Additionally, if the No Project Alternative were chosen, additional gas-fired power plants may be built, or existing gas-fired plants may operate longer. If the proposed project were not built, California would not benefit from the reduction in greenhouse gases that this facility would provide, and PG&E would not receive the 150 MW contribution to its renewable state-mandated energy portfolio.

NEPA No Action Alternative

Under NEPA, the No Action Alternative is used as a benchmark of existing conditions by which the public and decision makers can compare the environmental effects of the proposed action and the alternatives. Under the No Action Alternative, Western would deny the interconnection request and BLM would not grant a ROW. Like the No Project Alternative described above, under the No Action Alternative, the impacts of the RSEP project would not occur.

The No Project/No Action Alternative is addressed under the Environmental Analysis and Engineering Assessment of each resource element.

ALTERNATIVES CONSIDERED BUT NOT EVALUATED IN FURTHER DETAIL

This section considers potential alternatives to the proposed RSEP project that were evaluated, and but not retained for further analysis in this SA/DEIS for the following reasons: they were determined to not be feasible for meeting key project objectives; they are not yet commercially available; or they would not result in lesser impacts than the proposed action.

APPLICANT'S SITE ALTERNATIVES

Alternative sites were identified by the applicant in its Application for Certification (AFC). They are evaluated in this analysis and, based on the findings of the analyses, are not carried forward for detailed evaluation in this SA/EIS. The applicant-identified alternative sites are:

- Cadiz Alternative Site
- McCoy Alternative Site

The two sites are discussed in the following paragraphs.

Cadiz Alternative Site

Cadiz was identified by Rice Solar Energy LLC in the AFC as a potential alternative site for the proposed RSEP project; see **Alternatives Figure 5**. The 2,551-acre Cadiz Alternative Site is approximately 2 miles by 2 miles and occupies Sections 2 and 3 of Township 4N Range 14E and Sections 34 and 35 of Township 5N Range 14E. The 4 parcels are owned by Cadiz, Inc. (San Bernardino County APNs 055-63-2104, 055-63-1117, 055-63-2105, and 055-63-1116) and are adjacent to land administered by the BLM. The Cadiz Alternative Site is 6 miles south of the National Trails Highway (Route 66), 20 miles south of Interstate 40, 15 miles east of the town of Amboy, and six miles south of Chambless (which contains the nearest residences). The nearest town with full services is Twentynine Palms, approximately 65 miles to the southwest. The site can be accessed from Cadiz Road off of the National Trails Highway; approximately three miles of Cadiz Road would likely need paving or improvements.

The site is currently undeveloped, and does not appear to support recent uses. Adjacent lands (to the north and west) have been or are currently under agricultural production. San Bernardino County permits electrical power generation at the site (zoned AG-160), but requires a General Plan amendment to apply the Energy Facilities Overlay. Pacific Solar Investments Cadiz has filed a right-of-way application with the BLM for land adjacent to the south of the site. A 60-mile transmission interconnection would be required to connect to Western's Parker-Blythe #2 transmission line. A connection to Metropolitan Water District's (MWD) 230-kV line near the Iron Mountain substation would require an approximately 30-mile interconnection (SR 2009a, Sections 6.3.3 and 6.4; CH2MHill 2010a).

Neither the site nor the transmission connection (to either the Western or MWD line) would fall within the boundaries of the Mojave Trails Proposed National Monument, which is located to the north.

Environmental Assessment. As with the proposed RSEP site, the Cadiz site would result in the permanent loss of approximately 1,410 acres of desert habitat. According to the applicant, CNDBB records indicate the potential presence of Nelson's bighorn sheep, and vermilion flycatcher (which may also be present at the proposed site). The California Native Plant Society Inventory of Rare and Endangered Species indicates that Harwood's woollystar may occur within or near the Cadiz site. The Cadiz site, however, has a lesser degree of disturbance than the Rice site (which was previously used as an airfield), and would require a significantly longer transmission connection. Thus impacts to biological and visual resources are expected to be greater than at the proposed site.

Nearby potential historic cultural resources include: an old road that runs between Cadiz and Amboy; sections of the original Route 66; the BNSF railroad originally built in 1883 by the Atlantic and Pacific Rail Road Company; and the Atchison Topeka Santa Fe Railroad, which is now the Arizona and California Railroad (ARZC). The region was used by Native Americans, including Mojave and Chemehuevi groups. The Cadiz site is not listed as being eligible for the National Historic Register (CH2MHill 2010a). The California Historical Information System (CHRIS) conducted an archaeological and historic database search for the Cadiz site (CH2MHill 2010g); prior studies of the area indicate isolated archaeological finds and limited prehistoric use. Many of the historic

resources in the region are along the ARZC and other corridors. Impacts to cultural resources would likely be less than at the proposed site.

San Bernardino County land use designations and zoning would allow for development of a solar facility. However, a General Plan Amendment for an Energy Facilities Overlay would be required (SR 2009a).

Groundwater availability is unknown based on existing information. Impacts to other issue areas would likely be similar to the proposed site or mitigable with appropriate measures (SR 2009a).

Rationale for Elimination

The Cadiz site provides no substantial reduction in impacts over the proposed RSEP site and could create new impacts of its own. The lengthier transmission line would increase the potential for impacts to biological, cultural, and soil and water resources. In addition, it would not be located on disturbed land, unlike the proposed site. For these reasons, the Cadiz alternative site was eliminated from further consideration in this SA/DEIS.

McCoy Alternative Site

McCoy was also identified by Rice Solar Energy, LLC as a potential alternative site. See **Alternatives Figure 6**. The 1,905 acre-site is comprised of 5 parcels (Riverside County APNs 812-110-003, 812-110-009, 812-130-011, 812-161-020, and 812-220-025) in Township 5S, Range 21E, Sections 24 and 25; and in Township 5S, Range 22E, Sections 19 and 30. Four of the parcels are administered by the BLM, and the remaining parcel is under private ownership. The site occupies an area approximately 2 miles by two miles, minus one square mile in the southeastern corner. A circular heliostat field of 1,410 acres as proposed by the applicant would not fit within the site boundaries, and additional parcels would be needed to accommodate the project. The site is approximately 8 miles northwest of the city of Blythe, and 6 miles north of the Blythe airport. It sits in a valley framed by the northwest to southeast trending McCoy Mountains and Big Maria Mountains. Midland Road provides paved access to within 3.5 miles of the site. A network of unpaved roads extends to approximately one mile of the site. The nearest rural residence is two miles away, and the nearest residential cluster is five miles to the southeast, along the northwestern edge of the city of Blythe.

The site is currently open desert, and does not appear to support recent uses. It is not adjacent to degraded or impacted private lands. There are a number of BLM ROW applications within five miles of the McCoy site: Bull Frog Green Energy- Big Maria Vista to the north, Altera Black Hills to the northeast, Next Era Energy- McCoy to the west (may overlap with the McCoy Alternative site), and Chevron Energy- Blythe to the south. The site is located within the Southwest Area National Corridor; a one-mile transmission line would be needed to interconnect to Western's Parker-Blythe #2 transmission line to the west. A new interconnection substation would be required. (SR 2009a, Sections 6.3.2 and 6.4; CH2MHill 2010a)

Environmental Assessment

As with the proposed site, a project at the McCoy Alternative site would result in the permanent loss of 1,410 acres of desert habitat. The California Native Plant Society Inventory of Rare and Endangered Species indicates that California satintail (*Imperata brevifolia*) may occur partially within the site. Other species that have been observed to occur at the McCoy site or may potentially occur in the region include the desert tortoise, bitter hymenoxys, California leaf-nosed bat, California McCoy snail, dwarf germander, and vermilion flycatcher (CH2MHill 2010a). While the McCoy site would have a substantially shorter transmission interconnection (and less associated habitat disturbance), it would be located on undisturbed, open-space. Thus overall impacts to biological resources would be similar or reduced in comparison to the proposed RSEP site.

The McCoy site is not listed as being eligible for the National Historic Register, and the CHRIS database search found no archaeological or historic studies within 0.25 miles of the site boundary (CH2MHill 2010g). However, the applicant assumed that the site may contain cultural resources due to results from a nearby assessment. Water availability may be a concern at this site. City of Blythe treated wastewater infiltrates into Colorado River Aquifer and Colorado River water is fully allocated. Groundwater availability and potential for impacts to water resources are unknown (CH2MHill 2010a; SR 2009a). Visual impacts at the McCoy site would be slightly less than the RSEP due to a shorter transmission line connection; however, significant impacts would still be expected.

Rationale for Elimination

Since the McCoy site does not provide a substantial reduction in impacts over the proposed site, staff did not retain it for further consideration.

STAFF'S SITE ALTERNATIVES

Staff has identified sites throughout the California desert as potential locations for solar facility development. As with the Applicant's site alternatives, these alternative sites were evaluated, but based on findings from the analysis, not carried forward for detailed evaluation in this SA/EIS. Staff-identified alternative sites include the following:

- Agriculture Lands
- Blythe Mesa
- Broadwell Lake
- Gabrych
- Garlock Road
- Manix
- Mesquite Lake
- Siberia East
- South of Hwy 98

All of the sites would likely have adequate solar insolation, although detailed studies may be needed to determine if sufficient for CSP technology. Each site is discussed in the following paragraphs.

Agriculture Lands Alternative Site

The Agriculture Lands site is located in the Imperial Valley, southwest of El Centro. See **Alternatives Figure 7**. Although a large amount of disturbed land occurs in the Imperial Valley, the majority of it is active and viable farmland. In 2009, staff contacted local agencies and visited the area to consider farmland that is no longer economically viable or productive. Seven separate and unconnected parcels, totaling 4,600 acres, would comprise this alternative site. All parcels are on disturbed land; BL-1 has been fallow for several years with recovering native habitat whereas BL-2 through BL-7 consist of active agricultural lands with little or no native habitat. The site is subject to flooding from the Gleeson, Pinto, and Yuha Washes (Imperial County 2007). An approximately 7.5-mile interconnection would be required to reach the Imperial Valley Substation.

Environmental Assessment

The site consists of agricultural land, except for limited areas of Sonoran desert scrub and desert dry wash woodland (dominated by smoke tree (*Psorothamnus spinosus*)) in parcel BL-1. Five washes are thought to occur on the site. The site supports burrowing owl (*Athene cunicularia*) and flat tailed horned lizard (*Phrynosoma mcallii*), as well as sensitive plants such as annual rock-nettle (*Euclidia rupestris*) (CDFG 2009). Building a solar facility on the site would primarily impact agricultural lands, and as such, would have an impact on few listed and sensitive wildlife species and their habitats, with exception of burrowing owl, which is known to use agricultural land for foraging. As the surrounding area is highly disturbed with agriculture, impacts to biological resources would likely be less than at the proposed site.

Impacts to cultural resources would also likely be less than the RSEP site. The Imperial County General Plan EIR identifies most of the Agricultural Lands as having zero to rare cultural resources although some of Parcel BL-6 is located in an area identified as very sensitive for cultural resources (Imperial County 1993).

Given the site's agricultural nature, visual impacts would be reduced in comparison to the RSEP.

According to the Imperial County General Plan Land Use Element, industrial uses are not permitted on agricultural lands except for those directly associated with agricultural products and processes. Although Imperial County and the Imperial Irrigation District signed a 2009 Joint Resolution to encourage the growth of renewable energy in the Imperial Valley (Imperial County 2009a), the proposed project would not directly contribute to Imperial County's energy supplies and could be inconsistent with the resolution.

Rationale for Elimination

The Agriculture Land's parcels are of varying configurations. None of the parcels would be of adequate shape or size for a 150 MW solar power tower facility. Furthermore, Interstate 8 and Highway 98 bisect the larger of the parcels. The site would be suitable

for a solar project with smaller, discrete units, but would not be large enough to accommodate the RSEP project. Staff thus eliminated it from further consideration.

Blythe Mesa

The Blythe Mesa alternative site is northwest of Blythe, in the Palo Verde Valley. (It is in the general vicinity of the McCoy site discussed above). The site includes land that is no longer productive or economically viable for agriculture, as well as Solar Energy Study Areas on public lands identified in BLM Solar Energy Development Programmatic EIS documents (EERE and BLM 2010). Staff identified a 6,200-acre site that consists of three sections: a 2,780-acre southern section (Section 1), 2,000-acre eastern section (Section 2), and 1,280-acre northern section (Section 3). See **Alternatives Figure 8**. The acreage is primarily privately-owned, with a small portion administered by the BLM. The site, comprised of 50% agriculture, is primarily surrounded by undeveloped BLM land to the west. Agricultural land, as well as a Riverside County dumping site, golf course, and rural residences are located to the east.

Section 1, the largest of the three sections, consists of 56 parcels with 10 different landowners. It is accessed via Interstate 10 at the W. Hobson Way exit. There are no structures on this site, which is immediately north of the Blythe Energy Project Substation and approximately one mile north of the Blythe airport. A major wash made up of approximately 46 acres of desert dry wash woodland traverses this section. Section 1 also contains a disturbed wetland, two active detention basins, and three inactive detention basins.

Section 2 consists of 79 parcels and 23 landowners. It contains scattered residences and is accessed from Midland Road. It is crossed by the railroad tracks of the Arizona & California Railroad Company, and has a wash that appears to drain agricultural fields.

Section 3 consists of 17 parcels with 10 landowners, and contains scattered residences. It is crossed by the Atchison Topeka and Santa Fe railroad and Western's 161 kV Parker-Blythe #2 transmission line. A transmission interconnection (for any of the three sections) would likely follow the ROW of the Western line. The interconnection would trend south for 10-12 miles to reach the proposed Colorado River Substation. It would be located primarily on open space and through agriculture fields.

Environmental Assessment

CNDDDB records (CDFG 2009) indicate a number of sensitive species in the vicinity; desert tortoise (*Gopherus agassizii*) is reported adjacent to or within the northern and eastern portion of the site. The desert dry wash and areas of Sonoran creosote bush scrub would be permanently lost as a result of vegetation clearing and grading for a solar facility. However, approximately 85% of the alternative site is already moderately to highly disturbed as a result of cultivated fields, graded areas, wells, dirt roads, and railroads. As such, impacts to biological resources would likely be similar to that of the previously disturbed proposed site. The degree of ground disturbance also reduces the potential for currently undocumented cultural resources.

Sensitive receptors include the rural residences within Sections 2 and 3 and a residential area about 100 feet from the same sections. Noise impacts would be higher

than at the proposed site, where there are no nearby sensitive receptors. The southern section's one-mile proximity to the Blythe airport and the 653-foot tall central tower give the site a high potential to interfere with air traffic. The airport has two runways and for the 12-month period ending in 2006, aircraft operations averaged 69 takeoffs and landings per day (Solar Millennium 2009a).

Although this location is less remote than the RSEP site (and thus presents a greater contrast to the landscape), the location of sensitive receptors near the Blythe Mesa site would result in equally significant visual resource impacts should a project be located at this site.

Rationale for Elimination

As currently depicted, the sections of the Blythe Mesa Alternative site are either of inadequate size or shape for the proposed project. Section 1 has sufficient acreage, but is in an L-shape, not conducive for a concentrating solar power facility. Expansion of any of the three sections to accommodate the facility would involve encompassing more undisturbed desert habitat.

Furthermore, the proximity (of the only section with sufficient acreage) to the Blythe airport would likely make the site infeasible, particularly given the height of the central receiving tower. As such, staff is not retaining this site for further consideration.

Broadwell Lake

The Broadwell Lake alternative site is located on land administered by the BLM, approximately 8.5 miles north northwest of Interstate 40 at Ludlow, in unincorporated San Bernardino County. The site is approximately 1.5 miles east of the Kelso Dunes Wilderness, 7 miles north-northwest of the Bristol Mountains Wilderness, and 1 mile west of Broadwell Dry Lake. National Trails Highway (Route 66) and Interstate 40 are located approximately 8.5 miles south of the alternative site, and the historic Tonopah and Tidewater Railroad is located approximately 7 miles south of the site. The 5,000-acre site is of more than sufficient size for the proposed RSEP and is accessed via Crucero Road, a one-lane dirt road with an exit off Interstate 40 (DWR 2004). See **Alternatives Figure 9**.

The project would require a new substation and short interconnection to existing 230-kV and 500-kV SCE transmission lines, 1 mile northwest of the site.

Environmental Assessment

A project at Broadwell Lake would result in the permanent loss of relatively undisturbed vegetation (Mojave creosote scrub). CNDDDB records indicate that the site has potential habitat for the desert tortoise, but that there are no records for the species within 10 miles of site (CDFG 2009). Impacts to biological resources would likely be greater than for the previously disturbed proposed site.

The site is highly visible from the Kelso Dunes Wilderness and Bristol Mountain Wilderness, as there are no natural visual buffers. It is also visible from the Cady Mountains, including the Sleeping Beauty Subregion, and potentially visible from the Afton Canyon Natural Area (an Area of Critical Environmental Concern, and one of the

few places the Mojave River flows on the surface most of the year). Broadwell Lake also has a high level of recreational use, and receives many visitors. Impacts to visual resources and recreation would thus likely be higher than at the proposed site.

The Broadwell Lake site has twenty known archaeological, architectural, and historical sites, and is deemed to have a high sensitivity for Prehistoric and Historic Archaeological Resources (AIC 2008). The site would be located within the BLM North and Eastern Mojave (NEMO) Desert Management Plan, and the BLM Western Mojave Planning Area. Any significant unmitigated biological impacts caused by the project could make the site incompatible with the NEMO or Western Mojave Plans.

Rationale for Elimination

A project at the Broadwell Lake alternative site would have a significantly shorter transmission interconnection, but would develop undisturbed, public land. The site would have potentially higher environmental impacts – including to biological resources, visual resources, and land use and recreation – than the proposed site. Staff therefore eliminated it from further consideration.

Gabrych

The Gabrych alternative site is located in the Palo Verde Valley by the Colorado River, east of the City of Palo Verde. It is on 10 parcels of privately owned land (with only one landowner) making up 1,800 acres of land. The site is bordered to the south and east by the Colorado River, and would avoid the Harvey's Hole Fishing community that is adjacent to the river. A small sand/gravel mining operation just west of the residential area would also be avoided. The Riverside/Imperial County line forms the northern border. Active agriculture is found to the west and north of site. See **Alternatives Figure 10**.

The site is comprised primarily (85%) of active agricultural fields and active sheep grazing. The site also supports native habitat, including 38 acres of riparian scrub, 82 acres of arrowweed scrub, and 35 acres of desert saltbush scrub in the southwestern portion of the site and adjacent to the river. Seven acres of the Colorado River occur within the southern portion, and are jurisdictional to the U.S. Army Corps of Engineers and California Department of Fish and Game (CDFG). Other jurisdictional areas may include named on-site canals, riparian habitat along the D-23-1-3 and C Canals, and arrowweed scrub occurring in the southwestern corner of the site.

The site could connect with the SCE system at the proposed Colorado Substation through a new transmission line that would trend west from the site for approximately five miles then turn north for approximately 12 miles. The new transmission line would cross BLM land and active and fallow agricultural land, would be located adjacent to the existing Western 161 kV transmission line, and would be located within an existing CDD designated utility corridor. The transmission line would be within 500 feet of rural residences within the town of Palo Verde.

Environmental Assessment

CNDDDB records (CDGF 2009) identify the state-endangered (and of federal concern) Western yellow-billed cuckoo (*Coccyzus americanus occidentalis*) along the eastern

edge of the site, in riparian habitat associated with the river. The BLM-sensitive Yuma myotis (*Myotis yumanensis*) is reported along the southern boundary of site. A number of other special status species – including the Colorado River cotton rat (*Sigmodon arizonae plenus*) – occur to the west of the site. A solar project at the Gabrych site would need to avoid the native and potentially jurisdictional habitat in the site's western portion and along the river, thereby lessening potential impacts to special status species as well. Potential impacts may still occur to canals, which may result in impacts to waters of the State and/or waters of the U.S.

Less than 2% of the site has been systematically surveyed for cultural resources. However, the potential for unrecorded cultural resources is low, as the entire surface of the Gabrych Alternative site (with the exception of 233 acres) has been plowed or impacted by other agricultural activities. Impacts to cultural resources are likely to be less than at the proposed RSEP site.

A project at the site could result in temporary impacts to recreational users travelling down the Colorado River, and a direct impact on recreational users at Harvey's Fishing Hole. There would also be noise and visual impacts to Harvey's Fishing Hole. These visual impacts would likely be significant, similar to the proposed RSEP.

Rationale for Elimination

The site would be too narrow for the proposed project. Avoiding the native and potentially jurisdictional habitat in the western portion of the site (as well as along the Colorado River) further limits the dimensions of the site under consideration. Further study, however, could assess the feasibility of adding parcels to the north of the site. Since the site would not substantially reduce environmental impacts – and would have greater impacts to water resources, land use and recreation, visual resources, and noise and vibration – staff eliminated the site from further consideration.

Garlock Road

The Garlock Road Alternative site is located in southeastern Kern County's Fremont Valley, upstream of Koehn Dry Lake. It consists almost exclusively of fallow agricultural fields and is surrounded largely by undisturbed, native vegetation communities. The site encompasses five vegetation communities (in this approximate order of coverage from high to low): disturbed habitat, disturbed desert saltbush scrub, disturbed stabilized dunes, desert saltbush scrub, and developed. Disturbed habitat supports species such as mustard (*Sisymbrium* sp.), thistle (*Salsola* sp.), Mediterranean grass (*Schismus* sp.), and filaree (*Erodium* sp.). Less disturbed, surrounding areas are designated Desert Tortoise Critical Habitat.

The 2,000-acre site is comprised of 11 privately owned parcels in a rough U shape. See **Alternatives Figure 11**. There are a few isolated buildings onsite, as well as a handful of residential structures in the town of Garlock to the north of the site. It is unknown if they are occupied. The transmission interconnection to SCE's Kramer-Inyoken 230-kV transmission line would follow Garlock Road to the east and then Goler Road to the south; additional private party and BLM parcel crossings would be required.

Environmental Assessment

Special status species observations have been reported to the California Natural Diversity Database (CNDDDB) within five miles of the Garlock Road Alternative site. Listed species include desert tortoise (*Gopherus agassizii*), Western snowy plover (*Charadrius alexandrinus nivosus*) and Mohave ground squirrel (*Spermophilus mohavensis*) (CDFG 2009). The largely disturbed nature of the site, however, would limit wildlife use of the site for foraging, sheltering, breeding, or dispersal. However, since the site occurs in the center of Fremont Valley, wildlife may cross the site to travel between the mountains to the north and south or between the upper elevations in the valley to the east to Koehn Lake to the west. Impacts to biological resources would likely be similar to that of the proposed site, which is likewise on disturbed land surrounded by comparatively undisturbed desert habitat.

There are washes along the northern border and skirting the northwestern-most corner of the Garlock Road Alternative site. A focused delineation would be required to confirm jurisdiction since the wash may have connection to Koehn Lake. In relation to the wash, the northwestern portion of the site falls within a flood zone designated by the Federal Emergency Management Agency DFIRM (Digital Flood Insurance Rate Map) (Kern County 2010); use of affected parcels would likely require engineering measures to reduce the risk of flooding.

Constructing and operating a solar facility at the Garlock Road Alternative site could affect the site of Old Garlock (3.2 miles southwest of the current town location), and possibly one historic archaeological site, an historic can dump that may extend into the Garlock Road Alternative area. Because of the history of agricultural use of the entire site there is little potential for intact prehistoric or historic surface resources. Based on available information, impacts would be potentially less than or similar to that of the proposed site.

A project at this site would be visible to motorists and to users of designated offroad routes in the BLM Rand Mountains Fremont Valley Management Area (BLM 2008), offroad trails in the El Paso Mountains, and the southeast portion of the Red Rock Canyon State Park. Visual impacts would likely be significant and similar to the proposed RSEP project.

Rationale for Elimination

As configured, the site is not of adequate shape or size for the proposed RSEP. Additional small privately-owned parcels (with unclear levels of past disturbance) could be added to make the site more of a square shape; however the site may still not be large enough to accommodate the project without encroaching on undisturbed land or Desert Tortoise Critical Habitat. Furthermore the site provides no substantial reduction in impacts over the proposed site, and was dropped from further consideration.

Manix

The 2,600-acre alternative site would be located near Manix in San Bernardino County. See **Alternatives Figure 12**. The site is large enough for the proposed project with some room for adjustment. It contains a combination of privately-owned and BLM administered land, including some fallow and ruderal fields and developed areas. The

site wholly or partially comprises 47 parcels in Township 10N, Range 4E, Sections 6, 5, 7, 8, 17, 18, and 20; and Township 10N, Range 3E, Sections 12 and 13. Union Pacific railroad tracks (which parallel Interstate 15 and Yermo Road) form the northern border. The Mojave River and CDFG's Camp Cady Wildlife Area are located to the south. Mojave creosote bush scrub and atriplex scrub are the predominant vegetation types. Site access from Interstate 15 would be via the Harvard Road exit, Cherokee Road, Manix Road or Troy Road.

SCE's Coolwater-Dunn Siding 115 kV transmission line runs through the Manix alternative site, and would need to be realigned. A project at the site would require either an upgrade of the SCE transmission line or the construction of a new 10-mile 161 kV or 230 kV transmission line that would follow the existing corridor southwest to the Coolwater Substation.

Environmental Assessment

The Mojave River (which rarely flows in the Manix area) runs to the south of the site. There are patches of well developed riparian habitat and areas of no and poorly developed riparian habitat. Sensitive species – including Mojave fringe-toed lizard (*Uma scoparia*), desert tortoise (*Gopherus agassizii*), and Barstow woolly sunflower (*Barstow woolly sunflower*) – may occur in the vicinity of the alternative site (CDFG 2009). The Manix site, however, is generally made up of unsuitable to medium quality habitat for desert tortoise. It contains poor quality habitat for rare plants. Impacts to biological resources would likely be similar to that of the proposed site.

The site is adjacent to the Mojave River floodplain, a landscape context with moderately high frequency of prehistoric archaeological sites. Camp Cady, established by the U.S. Dragoons in 1860, is a California State Historical Landmark (No. 963-1). The former San Pedro, Los Angeles, and Salt Lake Railroad, now the Union Pacific Railroad, and segments of the Old Spanish Trail, the Mormon Trail, and the Mojave Road are thought to run through the area comprising the alternative site; the presence and integrity of these segments are presently unconfirmed. The site could thus have similar or slightly greater impacts to cultural resources than the proposed site.

Interstate 15 provides ready access to workers from the Barstow and Victor Valley areas, decreasing air emissions associated with commuting. Travel on Interstate 15, however, operates at a congested level on Friday afternoons, and a traffic analysis may result in the need to limit construction-period truck and commute traffic to off-peak periods. Construction equipment could travel to Barstow via railroad. In addition, the proximity to Interstate 15 would lead to prominent visibility for traffic in both directions. However, given the site's agricultural setting and proximity to motorists, visual impacts are likely to be similar to the proposed RSEP site.

Rationale for Elimination

The Manix site would be suitable in size and configuration for the proposed RSEP. Although portions of it have been previously disturbed, there would be no reduction in impacts (and slightly greater impacts in some issue areas) as compared to the proposed site. With 47 parcels, site control may be difficult to obtain. For these reasons, staff rejected Manix from further consideration.

Mesquite Lake

The Mesquite Lake alternative site is located in the Imperial Valley between the towns of El Centro and Brawley. As defined by the Mesquite Lake Specific Plan, Mesquite Lake is an area bordered by Keystone Road to the north, Highway 86 to the west, Harris Road to the south, and approximately 2,250 feet east of Old Highway 111 to the east. Transmission lines and roads occur within the site. The Mesquite Lake Plan Specific Area encompasses approximately 5,100 acres of land previously used primarily for agriculture. An additional 2,150 additional acres may be available immediately to the north. See **Alternatives Figure 13**.

The site is highly disturbed and is promoted for job-producing industrial land uses. Active and inactive agricultural land is comprised of hay fields, fallow fields, cattle grazing, a fish farm, processing plant, and equipment staging areas. There are several industrial facilities including the Holly Sugar Plant, Imperial Valley Resource Recovery Plant (an operational biomass facility), and a non-operational alternative-fuel-burning electric power plant. Four additional projects have applied for use of land in the Specific Plan. The Specific Plan contains 70 parcels owned by 52 landowners (EDAW 2006). Several canals (of which the largest is Rose Canal) traverse the site. A 25-mile interconnection would be needed to reach the Imperial Valley Substation.

Environmental Analysis

Three vegetation communities have been identified within the plan area: bush seepweed-iodine bush scrub, tamarisk scrub, and disturbed wetlands (EDAW 2006). CNDDDB records (CDFG 2009) indicate that sensitive species (within five miles of the site) may include the flat-tailed horned lizard (*Phrynosoma mcallii*), Yuma clapper rail (*Rallus longirostris yumanensis*), Western yellow bat (*Lasiurus xanthinus*), burrowing owl (*Athene cunicularia*), Gila woodpecker (*Melanerpes uropygialis*), Crissal thrasher (*Toxostoma crissale*), and Abrams' spurge (*Chamaesyce abramsiana*). Although construction of a solar power tower project would primarily occur on active and fallow agricultural lands, the burrowing owl is known to use agricultural land for habitat. Agriculture lands and fish ponds on the site also provide foraging, covert, and/or breeding habitat for migratory birds, including special-status bird species that may be present. The fields do not support habitat suitable for the flat-tailed horned lizard and Le Conte thrasher. The surrounding area is more intensely disturbed than the Rice Valley and overall impacts to biological resources would likely be similar or less than the proposed site.

Fifteen known archaeological, architectural, or historical sites would potentially be affected by construction and operation of a solar facility at the Mesquite Lake Alternative site (SES 2009m; EDAW 2006). However, areas where intensive cultivation for agricultural use have occurred would have a low probability for the presence of significant cultural resources due to deep excavation for drainage tiles and recurring surface disturbance (Imperial County 2006). As a significant portion of the site has been cultivated, development of a solar project at the site would likely impact fewer cultural resources than the proposed site.

Although the area includes active and fallow farmland, the loss of agricultural lands is likely to be a less than significant impact because the County has determined, since the

1970s, that the project area's highest and best use would be for medium and heavy industrial uses that would provide for more diversified employment opportunities and has rezoned the land for industrial use (EDAW 2006).

Rose Canal, its tributaries, and a few small areas of tamarisk scrub may be considered jurisdictional by the Corps and/or CDFG.

Given the more industrial nature of the site, visual impacts would likely be less than the proposed site.

Rationale for Elimination

The overall size and shape of the Mesquite Lake alternative site is sufficient for the RSEP project. However, it is traversed by three (34.5 kV, 92 kV, and 161 kV) Imperial Irrigation District transmission lines, Highway 111 and Dogwood Road (north to south arteries), the Rose Canal, and Union Pacific Railroad tracks. The highly disturbed site would be suitable for a solar project with smaller, discrete units, but not for the proposed solar power tower facility. As such, Mesquite Lake was not carried forward for detailed analysis.

Siberia East

The 4,000-acre Siberia East site is off the National Trails Highway (Route 66) in San Bernardino County. It is 8.5 miles southeast of Ludlow, five miles south of Interstate 40, and north of the Twentynine Palms Marine Corps Base. The National Trails Highway and Burlington Santa Fe railroad form the northeast border of the site. Barstow is 50 miles to the west. See **Alternatives Figure 14**.

Siberia East is on BLM-administered land, in the West Mojave Planning Area and in the California Desert Conservation Area. The land classification of Multiple Use would allow for a solar facility if NEPA requirements are met. BrightSource Solar has submitted an application to the BLM for a 1,600 MW solar project on a larger 15,000-acre area at the site.

The site consists primarily of undisturbed Mojave Desert scrub, specifically creosote bush scrub, mixed scrub and blackbush scrub (San Bernardino County 2006). The site also falls on the northern border of the Northern Colorado Desert Tortoise Recovery Unit. A 22-mile interconnection would need to be constructed, most likely to the SCE's Pisgah Substation to the northwest of the site.

Environmental Assessment

Siting the RSEP project at the Siberia East site would result in the permanent loss of relatively undisturbed vegetation, in what is currently open space, public land. Impacts to biological resources would likely be greater than that of the proposed site, and there could be direct and/or indirect impacts to the desert tortoise or its occupied habitat.

The San Bernardino Archaeological Information Center, in its record search report, stated the site was deemed to have a high sensitivity for prehistoric and historic archaeological resources, a low sensitivity for historic resources, and unknown sensitivities for cultural landscapes and ethnic resources (AIC 2008). A project at the

site would have a direct visual impact to the National Trails Highway (SBR-2910H) and visual impacts would likely be significant, similar to the proposed RSEP site.

Rationale for Elimination

The Siberia East site would not provide a reduction in impacts over the proposed site, and would likely have greater impacts to biological resources (particularly the desert tortoise). Furthermore, the site is on undisturbed public land whereas the proposed RSEP site is on previously disturbed private land. The Siberia East Alternative would require a longer (22-mile) transmission interconnection. For these reasons, staff eliminated the Siberia East Alternative from further consideration.

South of Hwy 98

The South of Highway 98 Alternative site is 5,000 acres located approximately four miles southeast of the greater El Centro region. See **Alternatives Figure 15**. It is on land withdrawn from BLM Management (in 1928) and administered by the Bureau of Reclamation. The site is sandwiched between Highway 98 to the north and the United States/Mexico border to the south. It is crossed by the concrete lined All-American Canal (parallel to the south of the highway). The 500 kV Southwest Powerlink Transmission Line is opposite the highway. Past seepage from the canal (prior to lining) has resulted in the formation of several hundred acres of wetland/riparian habitat on site.

Environmental Assessment

The site is partially disturbed (crossed by the canal, Southwest Powerlink, and off-road vehicle trails), and undeveloped on all sides, with the exception of Interstate 8 to the north.

Pursuant to the Imperial County General Plan, the All American Canal is considered a Significant Natural Area; it may also be considered a jurisdictional waterway. The canal supports year-round flows and is used by migratory waterfowl as well as resident species such as American coot (*Fulica Americana*) and great blue heron (*Ardea herodias*). The recent lining of the canal has resulted in the die-off of wetland vegetation in some areas, with continued loss expected. CNDDB species records (CDFG 2009) for five-miles of the site include one listed species: the federally endangered and state threatened Yuma clapper rail (*Rallus longirostris yumanensis*), and two California species of special concern: flat tailed horned lizard (*Phrynosoma mcallii*) and Yuma hispid cotton rat (*Sigmodon hispidus eremicus*). CNPS-listed sand food (*Pholisma sonorae*) and giant Spanish-needle (*Palafoxia arida* var. *gigantean*) also occur in the vicinity. As such, overall impacts to biological resources are expected to be slightly greater at the South of Highway 98 site than at the proposed RSEP site.

The Imperial County General Plan EIR identifies the site as having a moderate to light sensitivity for cultural resources (Imperial County 1993). A cultural resources records search conducted in 2009 for the site identified a total of 51 previously recorded cultural resources sites. Prior construction and maintenance of the All-American Canal may reduce the probability of undisturbed cultural resources at the site. This alternative site may have slightly less impact to cultural resources than the proposed site.

Visual impacts would likely be similar to the proposed RSEP site.

If water were to be obtained from the Seeley Waste Water Treatment Facility, construction of a 38-mile pipeline would be required.

Rationale for Elimination

The 5,000-acre site is long and narrow. The portion of the site south of the canal would be too narrow for the heliostat field of the proposed project. In addition, the site surrounds the BLM Tamarisk Long Term Visitor Area campground. A 30-mile transmission interconnection could be required to reach the Imperial Valley substation, with potential interference with agriculture operations and aerial spraying. An interconnection to the adjacent Southwest Powerlink is also a possibility, and an interconnection study would likely be required. As the site would not reduce environmental impacts, staff rejected it from further consideration.

ALTERNATIVE SOLAR GENERATION TECHNOLOGIES

In addition to the range of alternative sites discussed earlier, several alternative solar generation technologies were evaluated as potential alternatives to the proposed RSEP project. Although alternative solar generation technologies would achieve most of the project objectives, each would have different environmental or feasibility concerns. The following solar generation technologies were considered in this analysis:

- Stirling dish technology
- Parabolic trough
- Linear Fresnel technology
- Distributed solar technologies

Among the solar thermal technology alternatives, the linear Fresnel alternative has the potential for least ground disturbance due to its more compact configuration (reducing ground disturbance); however, the technology is proprietary and is not available to other applicants or developers. The distributed solar alternative would have fewer impacts than the proposed RSEP project because it would be located on already existing buildings or on already disturbed land. However, achieving 150 MW of distributed solar PV or solar thermal would depend on additional policy support, manufacturing capacity, and lower cost than currently exists to provide the renewable energy required to meet the California RPS requirements so additional technologies, like utility-scale solar thermal generation, would also be necessary.

These analyses assumed that the alternative technologies would be implemented on the site for the proposed RSEP site.

Stirling Dish Technology

Stirling dish technology uses a mirror array to convert thermal energy to electricity by concentrating and focusing sunlight on the receiver end of a Stirling engine. The curved dishes used to focus the sun's energy stand approximately 45 feet tall and occupy a maximum horizontal space of approximately 1,135 square feet (0.026 acres), with an anchored footprint of 12.5 square feet (assumed 4-foot diameter caisson). See

Alternatives Figure 16 for an illustration. The internal side of the receiver heats hydrogen gas, which expands; the pressure created by the expanding gas drives a piston, crankshaft, and drive shaft. The drive shaft turns a small electricity generator.

The entire energy conversion process takes place within a canister the size of an oil barrel. The generation process requires no water, and the engine does not produce emissions as no combustion takes place. Each concentrator consists of one Stirling engine mounted above one mirror array. Very little maintenance is required once each concentrator is installed, aside from periodic washing of the surface of the mirrors. In general, the Stirling system requires seven to nine acres of land per MW of power generated; a 150-MW Stirling engine field would require from 1,050 acres to 1,350 acres of land. Site preparation involves sinking a cement base with an embedded pedestal to support the dish (SES 2008). Each Stirling dish generates 25 kilowatts (KW) of power, so

6,000 dishes would be required to generate 150 MW. Each dish includes two major elements:

- **Solar Concentrator.** Large parabolic concentrators include 89 mirror facets attached to a frame by three point adjusting mounts (SES 2008). They are designed in five subassembly units for ease of transport and installation on site. Two small motors are attached to the pedestal and programmed to swivel the dish on two axes, following the sun's progress across the sky during the day.
- **Power Conversion Unit.** The Stirling engine's cylinder block incorporates four sealed cylinder assemblies along with coolers, regenerators, and heater heads (SES 2008). Concentrated solar energy heats up self-contained gas (hydrogen) in the power conversion unit, causing the gas to expand into the cylinders, moving the cylinders, and generating electricity. This cycle is repeated over and over as the engine runs at a steady rate of 1,800 rpm (SES 2008). Power is generated by heat transfer from the concentrated solar rays to the working gas in the engine's heater head, which converts the heat energy into mechanical motion. The generator of each unit in a utility-scale project is connected by underground transmission line to a small substation where the power can be transformed into a higher voltage for more efficient transmission across the grid.

Environmental Assessment

The land area required for a 150-MW Stirling engine power plant would range from 77% to a similar amount of the land required for the proposed RSEP project. In addition, Stirling engine technology allows for greater configuration flexibility and does not require the RSEP's circular arrangement. Localized cultural or biological resources could thus be more easily avoided.

It is not necessary to grade the entire parcel as only the 18-inch diameter pedestal of the Stirling engine requires level ground. However, it would still be necessary to grade permanent access roads between every two rows of Stirling engines due to the need for periodic mirror washing; the access road grading would result in vegetation removal and create a high contrast between the disturbed area and its surroundings.

The size and height of the Stirling mirrors would be similar to that of the heliostats used in the RSEP, and 6,000 Stirling engines would likewise introduce an industrial character and transformation of the site. Stirling technology would not include the 653-foot tall central receiver and tower, and impacts to visual resources would be comparatively less than those of the RSEP.

The area needed for a 150 MW Stirling engine power plant would be similar to approximately one-third less than the land requirement for the RSEP power plant, and the plant could have a more flexible configuration. Although grading requirements for the Stirling engines and solar concentrators are relatively small, grading for access roads would be extensive because access roads are required for every other row of Stirling engines (SES 2008a). Overall, impacts to recreation and land use, biological resources, and cultural resources would be slightly less than those of the RSEP facility. Visual impacts would also be slightly less without the proposed 653-foot tall central tower and receiver. However, Stirling engines would be similar to the proposed heliostats in size and height, and would be visible to viewers from the highway and nearby wilderness areas.

Rationale for Elimination

Because no substantial reduction in impact has been identified, the Stirling dish technology has been eliminated from further consideration as an alternative technology.

Parabolic Trough Technology

A parabolic trough system converts solar radiation to electricity by using sunlight to heat a fluid, such as oil, which is then used to generate steam. The plant consists of a large field of trough-shaped solar collectors arranged in parallel rows, normally aligned on a north-south horizontal axis. As illustrated in the photo below. Each parabolic trough collector has a linear parabolic-shaped reflector that focuses the sun's direct beam radiation on a linear receiver, also referred to as a heat collection element located at the focus of the parabola. See **Alternatives Figure 16** for an illustration. Heat transfer fluid within the collector is heated to approximately 740°F as it circulates through the receiver and returns to a series of heat exchangers where the fluid is used to generate high-pressure steam. The superheated steam is then fed to a conventional reheat steam turbine/generator to produce electricity.

A solar trough power plant generally requires land with a grade of less than 1%. On average, 4 to 8 acres of land are required per MW of power generated. A parabolic trough power plant would include the following major elements.

- **Parabolic Trough Collectors.** The parabolic trough collectors rotate around the horizontal north/south axis to track the sun as it moves through the sky during the day. Reflectors, or mirrors, focus the sun's radiation on a linear receiver/heat collection element, which is located along the length of the collector.
- **Solar Boiler.** Solar boilers are designed differently than conventional gas-fired boilers in that they are fueled with hot oil instead of hot gases. This design is similar to any shell and tube heat exchanger in that the hot heat transfer fluid is circulated through tubes and the steam is produced on the shell side.

- **Heat Transfer Fluid Oil Heater.** Due to the high freezing temperature of the solar field's heat transfer fluid (54°F), to eliminate the problem of oil freezing, an oil heater would be installed and used to protect the system during the night hours and colder months.

Parabolic trough power plants are the most established type of large solar generator.

They are currently being proposed throughout the California desert, and exist in several places, including the following examples:

- **Sunray Energy, Inc. Solar Energy Generating System** is located in Daggett, adjacent to an abandoned power tower facility. It generates 44 MW.
- **Kramer Junction Solar Energy Generating System** is located about 30 miles west of Barstow. The solar energy generating system projects are a series of utility-scale solar thermal electric power plants, which were designed and developed in the mid-1980s by LUZ Industries. The facility can produce 165 MW at full capacity (Solel 2008).

Environmental Assessment

Parabolic trough technology requires approximately four to eight acres per MW compared to the RSEP which requires about nine acres per MW. A 150 MW solar field using parabolic trough technology would thus encompass 600 to 1,200 acres of land, resulting in a 15% to 57% reduction in land use.

Cooling water demands using wet cooling could be on the order of 900 AFY for a 150 MW plant (6 AFY/MW). Dry-cooling could potentially only require 27 AFY for 150 MW (0.18 AFY/MW) (NRDC 2008c). This compares to the proposed RSEP's maximum water consumption of 180 acre feet per year.

Although this technology would have collectors that are approximately 30 feet high, in comparison to the 653-foot RSEP tower, visual impacts have been considered significant in the evaluation of recent solar thermal projects utilizing parabolic trough technology.

Rationale for Elimination

While parabolic trough technology is a viable renewable technology and could reduce the footprint of the project on the order of 12% to 56%, it would not significantly reduce the impacts of the proposed RSEP. Therefore, this alternative technology is eliminated from further consideration.

Linear Fresnel Technology

A solar linear Fresnel power plant converts solar radiation to electricity by using flat moving mirrors to follow the path of the sun and reflect its heat on the fixed pipe receivers located about the mirrors. See **Alternatives Figure 16**. During daylight hours, the solar concentrators focus heat on the receivers to produce steam, which is collected in a piping system and delivered to steam drums located in a solar field and then transferred to steam drums in a power block (Carrizo 2007). The steam drums transferred to the power block will be used to turn steam turbine generators and

produce electricity. The steam is then cooled, condensed into water, and recirculated back into the process.

Each row-segment is supported by large hoops that rotate independently on metal castors. Rotation of the reflectors would be driven by a small electrical pulse motor. Reflectors are stowed with the mirror aimed down at the ground during the night. The major components are:

- **Compact Linear Fresnel Reflector (CLFR) Solar Concentrator.** A solar Fresnel power plant would use Ausra's proprietary CLFR technology which consists of slightly curved linear solar reflectors that concentrate solar energy on an elevated receiver structure. Reflectors measure 52.5 by 7.5 feet (Carrizo 2007). There are 24 reflectors in each row. A line is made up of 10 adjacent rows and operates as a unit, focusing on a single receiver (Carrizo 2007).
- **Receiver Structure.** The receiver structure is approximately 56 feet tall (Carrizo 2007). It would carry a row of specially coated steel pipes in an insulated cavity. The receiver would produce saturated steam at approximately 518°F from cool water pumped through the receiver pipes and heated (Carrizo 2007). The steam would drive turbines and produce electricity.

Environmental Assessment

In general, the linear Fresnel technology requires four to five acres of land per MW of power generated. A 150 MW solar linear Fresnel field would require approximately 600 to 750 acres of land. This acreage is approximately 44% to 55% of that land required for the RSEP heliostat field. There would likely be a corresponding reduction in impacts to cultural resources, biological resources, soil and water resources, and other resources associated with land disturbance. The technology could also allow for a more flexible configuration, as the rows could be arranged to avoid sensitive areas.

A project using linear Fresnel technology would also reduce visual impacts, with 56 foot tall receivers (for the 177 MW CESF project) compared to a 653-foot tall central receiver for the RSEP. However, a Fresnel project would still industrialize a remote area, and be visible to viewers from the highway and nearby wilderness areas.

Rationale for Elimination

The Fresnel solar technology is a proprietary technology owned by Ausra, Inc. However, Ausra, Inc. has changed its focus to being a technology and equipment provider rather than an independent power developer and owner and will focus on medium-sized (50 MW) solar steam generating systems for customers including steam users, such as food processors and enhanced oil firms and utilities for power augmentation systems that deliver steam into existing fossil-fuel power plants. Given its proprietary nature and Ausra's focus on smaller-scale plants, this technology was not carried forward for detailed analysis.

Distributed Solar Technology

There is no single accepted definition of distributed solar technology. The 2009 *Integrated Energy Policy Report* (IEPR) defines distributed generation resources as "grid-connected or stand-alone electrical generation or storage systems, connected to

the distribution level of the transmission and distribution grid, and located at or very near the location where the energy is used.”

Distributed solar facilities vary in size from kilowatts to tens of megawatts but do not require transmission to get to the areas in which the generation is used. Distributed solar generation is generally considered to use photovoltaic (PV) technology although at slightly larger scales it is also being implemented using solar thermal technologies. Both technologies are considered below.

Distributed Solar PV Systems

Distributed solar by nature reduces the amount of new or disturbed land required as well as the quantity of water required. Most distributed rooftop PV systems in California are crystalline systems, and result in approximately 15% of sunlight converted to energy (SB 2009). The newer technology is thin film, which converts approximately 5% to 10% of sunlight to energy.

California currently has over 515 MW of distributed solar PV systems which cover over 40 million square feet (CPUC 2009). During 2008, 158 MW of distributed solar PV was installed in California, doubling the amount installed in 2007 (78 MW), and installation data suggests that at least the same amount of MW could be installed in 2009 as in 2008 with 78 MW installed through May 2009 (CPUC 2009).

California’s Investor Owned Utilities (IOUs) have announced significant aggregations of small-scale solar PV projects. Southern California Edison (SCE) has installed the first 3 MW of a planned 250 MW of solar panels on 2 square miles of commercial rooftop (in 150 installations) in the next five years (SCE 2009). In July 2008, San Diego Gas and Electric (SDG&E) proposed its Solar Energy Project, which it projects will result in up to 77 MW of new installed solar capacity in the San Diego load basin. SDG&E would build and operate 52 MW of rooftop solar and expects that customer opportunities resulting from this effort could result in the installation of up to an additional 25 MW of capacity under the California Solar Initiative (CSI) that would not have otherwise been built (SDG&E 2008).

In February 2009, PG&E announced plans to develop 500 MW of solar PV projects over the next five years. In contrast to the SCE and SDG&E programs, PG&E would largely focus on projects from 1 to 20 MW, with ground-mounted systems, rather than rooftop panels, playing a substantial role (PG&E 2009). In June 2009, the City of San Jose issued a solicitation for installation of 50 MW on city facilities and/or land, as part of its Green Vision goal of achieving 100% of electricity from renewable energy by 2020 (San Jose 2010).

A study prepared in 2007 by Navigant Consulting, Inc. (NCI) and the Energy Commission calculated the economic potential of distributed rooftop PV, by county, for new and retrofitted buildings (NCI 2007). **Alternatives Table 2** identifies those counties with the greatest retrofit¹ economic potential. The calculations are based on the most

¹ New construction economic potential was substantially less than retrofit potential.

favorable scenario using state subsidies (California Solar Initiative incentives) and new business models² favoring PV development.

ALTERNATIVES Table 2
California Counties with Greatest Economic Potential for Distributed Rooftop PV
(MW)

County	2010- Residential	2010 – Commercial	2016 – Residential	2016 – Commercial
Los Angeles	16	45	85	168
San Bernardino	14	11	181	99
San Diego	3	15	23	137
Orange	11	15	71	77
Riverside	4	7	33	60

Projections for potential distributed rooftop PV development in Riverside County of 93 MW in the year 2016 would be 62% of the RSEP’s 150 MW capacity. Without state subsidies and new business models favoring development, these projections are significantly lower. For instance, Riverside’s rooftop potential (retrofit and new construction) in 2016 would be 22 MW. With state subsidies, but without new business models, the County would have a potential of 28 MW (19% of the capacity of the proposed project) in 2016 (NCI 2007). Due to variable factors affecting the state’s economic climate, the projected economic potential in the county and statewide is uncertain. Even if feasible, multiple distributed PV installations would not meet the permitting timeframes identified for the proposed RSEP project.

Environmental Assessment

Installations of 150 MW distributed solar PV would require approximately 42 million square feet (approximately 1.5 square miles). Distributed solar PV is assumed to be located on already existing structures or disturbed areas so little to no new ground disturbance would be required and there would be few associated biological and cultural resources impacts.

Minimal grading or new access roads would be required and relatively minimal maintenance and washing of the solar panels would be required. As such, it is unlikely that the rooftop solar PV alternative would create erosion impacts. Some water would be required to wash the solar panels, especially with larger commercial rooftop solar installations; however, the commercial facilities would likely already be equipped with drainage systems. Therefore, the wash water would not contribute to runoff or to erosion.

² For this analysis, NCI used three of the seven business models developed with the Energy Commission’s Public Interest Energy Research Program: PV as an Appliance (where PV systems can be sold to a homeowner and incorporated into the home like an appliance as “plug and play”), No Hassle PV (where a single entity bundles the system design, purchase, permitting, rebate application, installation, maintenance, and financing into one transaction for the customer), and PV Consumer Finance (in which initial PV system costs are financed using standard consumer finance models).

Because most PV panels are black to absorb sun, rather than mirrored to reflect it, glare would be lessened. Additionally, the distributed solar PV alternative would not require the additional operational components, such as dry-cooling towers, substations, transmission interconnection, and maintenance and operation facilities with corresponding visual impacts. Solar PV panels would be visible to passing residents and may be viewed by a larger number of people.

Consideration of CEQA/NEPA Criteria

Reduction of Impacts. Distributed solar technology is assumed to be located on already existing structures or disturbed areas so little to no new ground disturbance would be required; there would be few associated impacts to biological and cultural resources. Additionally, impacts to soils and waters as well as visual resources would be reduced.

Meet Most Project Objectives. A distributed solar technology alternative, if constructed at 150 MW, would meet the Energy Commission project objectives to operate 150 MW of renewable power in California capable of selling competitively priced renewable energy. The solar technology would not necessarily meet the objective to locate the facility in areas of high solar intensity, because the distributed technology could be located throughout the State.

Feasibility. The rate of PV manufacturing and installation is expected to continue to grow very quickly. However, given that there are currently only about 500 MW of distributed solar PV in California, the addition of 150 MW to eliminate the need for the RSEP cannot be guaranteed. This would require an even more aggressive deployment of PV at more than double the historic rate of solar PV than the California Solar Initiative program currently employs. Challenges to an accelerated implementation of distributed solar PV are discussed below.

- **RETI Consideration of Subsidies, Tariffs, Cost, and Manufacturing.** The RETI Discussion Draft Paper *California's Renewable Energy Goals – Assessing the Need for Additional Transmission Facilities* published with the RETI Final Phase 2A Report (September 2009), addresses the likelihood of a scenario of sufficient distributed solar PV to remove the need for utility scale renewable development. This discussion paper identified the factors likely to influence the pace of large scale deployment of distributed solar PV: subsidies, feed-in tariffs, manufacturing and installation cost, and manufacturing scale-up.
- **Cost.** The 2009 IEPR states that solar PV technology has shown dramatic cost reductions since 2007, and is expected to show the most improvement of all the technologies evaluated in the 2009 IEPR model, bringing its capital cost within range of that of natural gas-fired combined cycle units. However, the CPUC 33% *Renewables Portfolio Standard Implementation Analysis Preliminary Results* considered a number of cases to achieve a 33% RPS standard. The results of this study state that the cost of a high distributed generation case is significantly higher than the other 33% RPS alternative cases. The study explains that this is due to the heavy reliance on solar PV resources which are more expensive than wind and central station solar.

- **Tariffs.** The IEPR discusses the need to adjust feed-in tariffs to keep downward pressure on costs. Feed-in tariffs should be developed based on the size and type of renewable resources, given that the cost of generating energy from a 100-MW wind farm is less than the cost of generating to ensure a good mix of new renewable energy projects. According to the report, differentiating feed-in tariffs by type and size can ensure a good mix of new renewable energy projects and avoid paying too much for some technologies and too little for others.
- **Limited Installations.** Examples of large scale distributed solar projects are still limited. In the spring of 2008, SCE proposed 250 to 500 MW of rooftop solar PV to be installed in five years. As of January 2010, SCE had installed only 3 MW. As the 2009 IEPR points out, the potential for distributed resources remains largely untapped and integrating large amounts of distributed renewable generation on distribution systems throughout the State presents challenges.
- **Electric Distribution System.** The State's electric distribution systems are not designed to easily accommodate large quantities of randomly installed distributed generation resources at customer sites. Accomplishing this objective efficiently and cost-effectively will require the development of a new transparent distribution planning framework. The 2009 IEPR makes a number of recommendations to support the integration of distributed generation into the California grid, expand feed-in tariffs, and support the efforts to achieve the RPS goals as a whole. It also recommends supporting new renewable facilities and the necessary transmission corridors and lines to access the facilities.

In testimony filed by the Center for Biological Diversity in the Ivanpah Solar Electric Generating System (ISEGS) proceeding [Docket No. 07-AFC-5], Bill Powers stated his disagreement with the conclusions of the ISEGS Alternatives FSA/DEIS section addressing distributed solar PV. Mr. Powers believed that the technology and manufacturing capacity would be adequate to develop 400 MW of distributed PV, and that the distribution system would be able to accommodate the additional distributed generation. He presented numerous examples of California utility programs that have committed to development of hundreds of megawatts of additional distributed solar PV.

The conclusion of this section is that, while it will very likely be possible to achieve 150 MW of distributed solar energy over the coming years, the very limited numbers of existing facilities make it difficult to conclude with confidence that it will happen within the timeframe required for the RSEP project. As a result, this technology is eliminated from detailed analysis in this SA/EIS.

ALTERNATIVE RENEWABLE TECHNOLOGIES

Non-solar renewable generation technologies were considered as potential alternatives to the proposed RSEP project. The following renewable generation technologies were considered in this analysis:

- wind energy
- geothermal energy
- biomass energy

- tidal energy
- wave energy

The non-solar renewable technologies alternatives (wind, geothermal, biomass, tidal, wave) would either be infeasible for meeting key project objectives at the scale of the proposed RSEP project, or would not eliminate impacts caused by the project without creating impacts in other locations. Specifically, wind energy that would be viable at some locations in Riverside County could create its own impacts to biological, visual, cultural, and soil resources.

Wind Energy

Wind carries kinetic energy that can be used to spin the blades of a wind turbine rotor and an electrical generator, which then feed alternating current (AC) into the utility grid. Most state-of-the-art wind turbines operating today convert 35% to 40% of the wind's kinetic energy into electricity. A single 1.5-MW turbine operating at a 40% capacity factor generates 2,100 MWh annually.

Wind turbines currently being manufactured have power ratings ranging from 250 watts to 5 MW, and units larger than 7 MW in capacity are now under development (AWEA 2008). The average capacity of wind turbines installed in the United States in 2007 was 1.65 MW (EERE 2008). The perception of wind as an emerging energy source reached a peak in the early 1980s, when wind turbine generators to convert wind power into electricity were being installed in California at a rate of nearly 2,000 per year. Progress slowed a few years later, however, as start-up tax subsidies disappeared and experience demonstrated some deficiencies in design. At the present time, technological progress has caught up, contributing lower cost and greater reliability.

This technology is well developed and can be used to generate substantial amounts of power. There is now approximately 2,490 MW of wind-generated power being produced in California (AWEA 2008).

Modern wind turbines represent viable renewable alternatives to solar energy projects in the region as exemplified by the number of wind projects applications pending at the BLM in California. The BLM has received approximately 64 applications for wind projects in the California Desert District as of August 2009, for use of over 457,769 acres of land (BLM 2009). A total of three applications have been submitted for Riverside County, estimated at 94 MW of generation (CEC 2010).

Environmental Assessment

Wind turbines can create adverse environmental impacts, as summarized below (AWEA 2008):

- Wind energy requires between 5 and 17 acres per MW of energy created. As such a nominal 150 MW power plant would require between 750 and 2550 acres. However, wind turbine footprints typically use only 3-5% of the total area.
- Erosion can be a concern in certain habitats such as the desert or mountain ridgelines. Standard engineering practices can be used to reduce erosion potential.

- Birds collide with wind turbines. Avian deaths, particularly raptors, are a substantial concern depending on raptor use of the area.
- Wind energy can negatively impact birds and other wildlife by fragmenting habitat, both through installation and operation of wind turbines themselves and through the roads and power lines that are required to support the turbines.
- Bats collide with wind turbines. The extent of bat mortality depends on turbine placement and bat flight patterns.
- Visual impacts of wind turbines can be significant, and installation in scenic and high traffic areas can result in strong local opposition. Other impressions of wind turbines are that they are attractive and represent clean energy.

Approximately 750 to 2,550 acres of land would be required for a 150 MW wind electricity power plant. While wind plants would not necessarily impact the same types of wildlife and vegetation as the proposed RSEP plant, the significant acreage necessary for a 150 MW wind plant would still cause significant habitat loss in addition to potentially significant impacts from habitat fragmentation and bird and bat mortality. Wind turbines are often over 400 feet high for 2-MW turbines. As such, any wind energy project would be highly visible, similar to the proposed RSEP.

Rationale for Elimination

While wind electricity generation is a viable and important renewable technology in California, it would not reduce the large-scale ground disturbance and visual impacts associated with the RSEP project. Therefore wind generation was eliminated from further consideration in this SA/DEIS. Furthermore, it is part of a renewable energy supply mix along with solar thermal, which staff believes will be needed to meet statewide RPS requirements.

Biomass Energy

Electricity can be generated by burning organic fuels in a boiler to produce steam, which then turns a turbine; this is biomass generation. Biomass can also be converted into a fuel gas such as methane and burned to generate power. Wood is the most commonly used biomass for power generation. Major biomass fuels include forestry and mill wastes, agricultural field crop and food processing wastes, and construction and urban wood wastes. Several techniques are used to convert these fuels to electricity, including direct combustion, gasification, and anaerobic fermentation. Biomass facilities do not require the extensive amount of land required by the other renewable energy sources discussed, but they generate much smaller amounts of electricity.

Currently, nearly 19% of the state's renewable electricity derives from biomass and waste-to-energy sources (CEC 2007). Most biomass plant capacities are in the 3- to 10-MW range and typically operate as baseload capacity. The average size of a sales generation biomass plant is 21 MW (CBEA 2008). Unlike other renewable sources, the locational flexibility of biomass facilities would reduce the need for substantial transmission investments. Colmac Energy, Inc. currently operates a 47 MW plant in Riverside County's Coachella Valley. The plant, in operation since 1992, consumes approximately 325,000 tons per year of wood, agricultural, landscaping, and construction waste (Biomass Power Association 2009).

Solid fuel biomass (total of 555 MW) makes up about 1.75% of the state's electricity, and landfill methane gas generation (total of 260 MW) makes up about 0.75%. Existing landfills not now producing electricity from gas could add a maximum of about 170 MW of new generation capacity (CBEA 2008).

Environmental Assessment

Generally, small amounts of land are required for biomass power facilities; however, a biomass facility should be sited near a relatively large source of biomass to minimize the cost and truck emissions associated with bringing the biomass waste to the facility.

Operational noise impacts, originating from truck engines entering and exiting the facility repeatedly on a daily basis, may be a concern. Other operations of the biomass facilities, while internal to the main structure, can result in increased noise due to the material grinding equipment.

The emissions due to biomass fuel-fired power plant operation are generally unavoidable. Direct impacts of criteria pollutants could cause or contribute to a violation of the ambient air quality standards. Significant impacts can potentially occur for PM10 and ozone because emissions of particulate matter and precursors and ozone precursors could contribute to existing violations of the standards for those criteria pollutants. Biomass/biogas facility emissions could also adversely affect visibility and vegetation in federal Class I areas or state wilderness areas as a result of significantly deteriorating air quality related values in the wilderness areas. Toxic air contaminants from routine operation would also cause health risks that could adversely affect sensitive receptors in the local area of the plant.

Rationale for Elimination

Most biomass facilities produce only small amounts of electricity (in the range of 3 to 10 MW) and so could not meet the project objectives. Biomass facilities also generate significant air emissions and require numerous truck deliveries to supply the plants with the biomass waste materials. Also, in waste-to-energy facilities, there is some concern regarding the emission of toxic chemicals, such as dioxin, and the disposal of the toxic ash that results from biomass burning. Therefore, this technology is not analyzed in detail in this SA/DEIS as an alternative to the RSEP project.

Geothermal

Steam or high-temperature water from geothermal reservoirs is harnessed to drive steam turbine/generators. Geothermal plants range in size from under 1 MW to 200 MW. Geothermal plants provide highly reliable base-load power, with capacity factors from 90% to 98%. Plants, however, must be built near geothermal reservoir sites, as steam and hot water cannot be transported long distances without significant thermal energy loss. Geothermal plants are currently operating in the California counties of Lake, Sonoma, Imperial, Inyo, Mono, and Lassen. Larger geothermal areas in the Mojave Desert are in Coso Hot Springs (southwestern Inyo County) and Imperial County (CEC 2005).

The state has an estimated potential of more than 4,000 MW additional geothermal output (CEC 2009b), although few projects are currently proposed. Multiple (i.e. two to

five) smaller geothermal projects – and related transmission lines, wells, and pipelines – would likely be required to achieve the 150 MW capacity of the proposed RSEP project.

Environmental Assessment

Concerns regarding geothermal power plants include air quality, hazardous materials, and geology. Benefits from geothermal power plants include an increased reliability and less ground disturbance than some renewable resources, including solar.

Toxic air contaminants and odors would be emitted as a result of fuel combustion in construction-related equipment and vehicles and as a result of geothermal steam released during well testing. Hydrogen sulfide (H₂S) in geothermal steam is a toxic air contaminant and a colorless, flammable, poisonous compound with a characteristic rotten-egg odor. H₂S is toxic at concentrations higher than 30 parts per million (ppm) (CEC 2003), and fatal at concentrations above 100 ppm. However, H₂S is now often abated at geothermal power plants, resulting in a conversion of almost all of the H₂S into elemental sulfur (GEA 2007). Ammonia also occurs in geothermal steam and is a toxic air contaminant with a pungent, penetrating odor. Ammonia is a precursor pollutant to particulate matter in the ambient air.

Geothermal power projects require less ground disturbance than almost any other energy source, typically from about 0.2 to 0.5 acres per MW; however, geothermal plants must be built where the resource is since the steam cannot be piped long distances without significant heat loss. This results in a highly secure and predictable fuel supply (95% or higher availability (CEC 2003)), but inflexibility in siting. It may also result in a long interconnection requirement to reach a transmission system.

The construction emissions resulting from building multiple geothermal facilities would be similar to the type of construction emissions for the RSPP project. However, the geothermal facilities would require fewer acres of ground disturbance. Operational emissions from the geothermal facilities would be greater than those of the proposed RSEP project because of the potential emissions of ammonia and H₂S. However, with mitigation, these impacts would be reduced.

Because of the minimal ground disturbance required from the geothermal facilities themselves, impacts to biological resources and cultural resources would likely be minimized compared to the heliostat field for the RSEP. However, in that two to five geothermal facilities would be required for provision of 150 MW, depending on the locations of the new facilities, more transmission lines and switchyards with corresponding potential impacts (i.e., biological, cultural, soil & water, land use, visual) may be required for grid interconnection, when compared to the proposed RSEP.

Rationale for Elimination

Geothermal generation is a commercially available technology and is important for California's renewable energy future because it provides baseload power that is available 24 hours a day. Although geothermal facilities can be developed with substantially less ground disturbance than that needed for the RSEP, transmission infrastructure for multiple facilities (depending on their locations) can increase environmental impacts.

Despite the encouragement provided by Renewable Portfolio Standard targets and ARRA funding, few new projects have been proposed and no geothermal projects are included on the Renewable Energy Action Team list of projects requesting ARRA funds. Therefore, while the technology is clearly feasible and additional development is expected, the technology is not retained for detailed analysis in this SA/DEIS.

Tidal Energy

The oldest technology to harness tidal power for the generation of electricity involves building a dam, known as a *barrage*, across a bay or estuary that has large differences in elevation between high and low tides. Water retained behind a dam at high tide generates a power head sufficient to generate electricity as the tide ebbs and water released from within the dam turns conventional turbines.

Certain coastal regions experience higher tides than others. This is a result of the amplification of tides caused by local geographical features such as bays and inlets. In order to produce practical amounts of power for tidal barrages, a difference between high and low tides of at least five meters is required. There are about 40 sites around the world with this magnitude of tidal range. The higher the tides, the more electricity can be generated from a given site and the lower the cost of the electricity produced. Worldwide, existing power plants using tidal energy include a 240-MW plant in France, a 20-MW plant in Nova Scotia, and a 0.5-MW plant in Russia (EPRI 2006).

Tidal Fences

Tidal fences are effectively barrages that completely block a channel. If deployed across the mouth of an estuary, they can be very environmentally destructive. However, in the 1990s, their deployment in channels between small islands or in straights between the mainland and islands has increasingly been considered a viable option for the generation of large amounts of electricity.

The advantage of a tidal fence is that all the electrical equipment (generators and transformers) can be kept high above the water. Also, by decreasing the cross-section of the channel, current velocity through the turbines is significantly increased.

The United Kingdom is currently considering the feasibility of tidal energy across the Bristol Channel. The feasibility study began with the consideration of the Severn tidal barrage. The barrage would work similarly to a dam which generates hydro electric power by holding water back before it is allowed to flow at speed through a pipe at the base of the dam to drive the turbines (BBC 2007). Since then, alternative tidal projects have been proposed, including a tidal fence that would allow shipping to move freely and keep ports at Cardiff and Bristol open (BBC 2008). The results of the feasibility study are expected to be published in 2010; however, preliminary results from the Sustainable Development Commission confirmed the potential of the huge Severn tidal range to generate approximately 5% of United Kingdom's electricity (BIS 2009).

Tidal Turbines

Tidal turbines are the chief competition to the tidal fence. Looking like an underwater wind turbine, they offer a number of advantages over the tidal fence. They are less

disruptive to wildlife, allow small boats to continue to use the area, and have much lower material requirements than tidal fences.

Tidal turbines function well where coastal currents run at 2 to 2.5 meters per second (slower currents tend to be uneconomic while larger ones stress the equipment). Such currents provide an energy density four times greater than air, meaning that a 15-meter-diameter turbine will generate as much energy as a 60-meter-diameter windmill. In addition, tidal currents are both predictable and reliable, a feature which gives them an advantage over both wind and solar systems. The tidal turbine also offers significant environmental advantages over wind and solar systems because the majority of the assembly is hidden below the waterline and all cabling is along the sea bed.

There are many sites around the world where tidal turbines could be effectively installed. An ideal site is close to shore (within 1 kilometer) in water depths of about 20 to 30 meters. In April 2007, the first major tidal-power project was installed in the United States off New York City's Roosevelt Island (Fairley 2007). Turbines such as those used in New York City use in-flow turbines, thereby lessening the environmental impacts. A study conducted in 2006, *System Level Design, Performance, Cost and Economic Assessment – San Francisco Tidal In-Stream Power Plant*, concluded that a tidal plant located under the Golden Gate Bridge could create approximately 35 MW of power with no significant impacts to the environment and recommended further research and development into both ocean energy technology and a pilot project in San Francisco (EPRI 2006a).

Environmental Assessment

Tidal technologies, especially tidal fences, have the potential to cause significant biological impacts, especially to marine species and habitats. Fish could be caught in the unit's fins by the sudden drop in pressure near the unit. The passageways, more than 15 feet high and probably sitting on a bay floor, could squeeze out marine life that lives there or alter the tidal flow, sediment build-up, and the ecosystem in general. Even the in-flow turbines can have adverse impacts on marine systems. The in-flow turbines off New York City must undergo environmental monitoring for 18 months to ensure the turbines will not create adverse impacts to the river's marine wildlife. Also, depending on the location of the tidal technology, commercial shipping could be disrupted during construction.

The reduced tidal range (difference between high and low water levels) resulting from tidal energy generation can destroy inter-tidal habitat used by wading birds. Sediment trapped behind the barrage could also reduce the volume of the estuary over time.

Rationale for Elimination

Tidal fence technology is a commercially available technology in Europe, although limited to areas that are adjacent to a body of water with a large difference between high and low tides, and it can result in significant environmental impacts to ocean ecosystems. In-flow tidal turbines are a relatively new technology and are not considered an alternative to the RSEP project because they are an unproven technology at the scale that would be required to replace the proposed project. Additionally, the potential for adverse impacts of tidal turbines is still under review, as demonstrated by the pilot project under environmental monitoring in New York.

Therefore, this technology is not analyzed in detail in this SA/EIS as an alternative to the RSEP project.

Wave Energy

Wave power technologies have been used for nearly 30 years. Setbacks and a general lack of confidence have contributed to slow progress towards proven devices that would have a good probability of becoming commercial sources of electrical power using wave energy.

The highest energy waves are concentrated off the western coasts of the United States in the 40° to 60° latitude range north and south. The power in the wave fronts varies in these areas between 30 and 70 kilowatts per meter (kW/m) with peaks to 100 kW/m in the Atlantic southwest of Ireland, the Southern Ocean and off Cape Horn. Many wave energy devices are still in the research and development stage and would require large amounts of capital to get started. Additional costs from permitting and environmental assessments also make wave energy problematic (WEC 2007). Nonetheless, wave energy is likely to increase in use within the next 5 to 10 years.

The total power of waves breaking on the world's coastlines is estimated at two to three million MW. In favorable locations, wave energy density can average 65 MW per mile of coastline. Three approaches to capturing wave energy are:

- **Floats or Pitching Devices.** These devices generate electricity from the bobbing or pitching action of a floating object. The object can be mounted to a floating raft or to a device fixed on the ocean floor.
- **Oscillating Water Columns.** These devices generate electricity from the wave-driven rise and fall of water in a cylindrical shaft. The rising and falling water column drives air into and out of the top of the shaft, powering an air-driven turbine.
- **Wave Surge or Focusing Devices.** These shoreline devices, also called tapered channel or tapchan systems, rely on a shore-mounted structure to channel and concentrate the waves, driving them into an elevated reservoir. Water flow out of this reservoir is used to generate electricity, using standard hydropower technologies.

In December 2007, PG&E signed a power purchase agreement with Finavera Renewables, which had planned to operate a wave farm approximately 2.5 miles off the coast of Eureka, California. The agreement was for 2 MW of power beginning in 2012. On October 16, 2008, the California Public Utilities Commission rejected PG&E's request for approval of a renewable resource procurement contract with Finavera Renewables because, among other reasons, the CPUC concluded the project had not been shown to be viable. As stated in that decision, there is significant uncertainty surrounding wave technology and the wave energy industry is at a beginning stage (CPUC 2008). The CPUC did authorize up to \$4.8 million for PG&E to undertake its WaveConnect project in Decision D.09-01-036. WaveConnect is designed to document the feasibility of a facility that converts wave energy into electricity by using wave energy conversion (WEC) devices in the open ocean adjacent to PG&E's service territory.

In January 2010, the California State Lands Commission and the Federal Energy Regulatory Commission issued a Request for Statements of Interest to prepare an environmental document for the PG&E WaveConnect project discussed above. PG&E has selected a wave energy project siting area that is between 2.5 and 3.0 nautical miles (nm) from the shore in Humboldt County. WaveConnect consists of: (1) wave energy converters (WECs) including multi-point catenary moorings and anchors; (2) marker buoys, navigation lights, and environmental monitoring instruments; (3) subsea electrical cables extending on-shore to (4) land-based power conditioning equipment; (5) an above-ground transmission line and interconnection to the electrical grid; (6) data acquisition and telemetry equipment; and (7) security and safety equipment.

Environmental Assessment

The environmental impacts of wave power have yet to be fully analyzed. A recent study published by the U.S. Department of Commerce and National Oceanic and Atmospheric Administration listed a number of potentially significant environmental impacts created by wave power (Boehlert 2008):

- Significant reduction to waves with possible effects to beaches (e.g. changes to sediment transport processes).
- The use of buoys may have positive effects on forage fish species, which in turn could attract larger predators. Structures need to be designed to reduce the potential entanglement of larger predators, especially marine turtle species.
- Modifications to water circulation and currents may result in changes to larval distribution and sediment transport.
- Wave energy development may affect community structures for fish and fisheries.
- Lighting and above-water structures may result in marine bird attraction and collisions and may alter food webs and beach processes.
- A diversity of concerns would arise regarding marine mammals including entanglement issues.
- Energy-absorbing structures may affect numerous receptors and should avoid sensitive habitats.
- Potential hazards from chemicals used in the process must be addressed both for spills and for a continuous release such as in fouling paints.
- New hard structures and lighting may break loose and increase debris accumulation.
- Impacts on fish and marine mammals caused by noise coming from the buoys should be understood and mitigated.
- Electromagnetic effects may affect feeding or orientation and should be better understood.
- Impact thresholds need to be established. As projects scale up in location or implementation, new risks may become evident.

Rationale for Elimination

Wave energy is new and may not be technologically feasible; as stated above, PG&E is proposing to sponsor a project to test the feasibility of harnessing wave energy. Additionally, wave power must be located where waves are consistently strong; even then, the production of power depends on the size of waves, which result in large differences in the amount of energy produced. Wave technology is not considered an alternative to the RSEP project because it is an unproven technology at the scale that would be required to replace the proposed project and because it may also result in substantial adverse environmental impacts. Therefore, this technology is not analyzed in detail in this SA/DEIS as an alternative to the RSEP project.

ALTERNATIVE METHODS OF GENERATING OR CONSERVING ELECTRICITY

Nonrenewable generation technologies that require use of natural gas, coal, or nuclear energy would not achieve the key project objective for the proposed RSEP project to provide clean, renewable, solar-powered electricity and to assist meeting obligations under California's RPS Program.

While these generation technologies would not achieve this key objective, they are described briefly in this section to present this information to the public and decision makers. Conservation and demand-side management are also briefly addressed in this section.

The following topics were considered in this analysis:

- natural gas
- coal
- nuclear energy
- conservation and demand-side management

Of the three nonrenewable generation alternatives (natural gas, coal, and nuclear), only natural gas-fired power plants would be viable alternatives within California. However, gas-fired plants would fail to meet a major project objective to construct and operate a renewable power generating facility in California capable of selling competitively priced renewable energy consistent with the needs of California utilities and would therefore not achieve the purpose and need of the project. Because these alternatives would not support renewable power generation within California, and could have significant environmental impacts of their own, they were eliminated from further consideration.

Natural Gas Generation

Natural gas power generation accounts for approximately 22% of all the energy used in the United States and comprises 40% of the power generated in California (CEC 2007). Natural gas power plants typically consist of combustion turbine generators, heat recovery steam generators, a steam turbine generator, wet or dry cooling towers, and associated support equipment. An interconnection with a natural gas pipeline, a water supply, and electric transmission are also required. A gas-fired power plant generating 150 MW would generally require about six acres of land.

Environmental Assessment

Natural gas power plants may result in numerous adverse environmental impacts such as the following.

- Overall air quality impacts would increase because natural gas-fired power plants can contribute to local violations of the PM10 and ozone air quality standards, and operational emissions could result in toxic air contaminants that could adversely affect sensitive receptors. Net increases in greenhouse gas emissions due to natural gas-firing in the conventional power plants would also be substantial.
- Environmental justice may be a concern. Gas-fired power plants tend to be located in developed urban areas that are zoned for heavy industry. In some instances, low-income and minority populations are also located in such areas.
- To avoid adverse land use impacts, natural gas-fired power plants must be consistent with local jurisdictions' zoning.
- Several hazardous materials, including regulated substances (aqueous ammonia, hydrogen, and sulfuric acid), would be stored at a natural gas power plant during operation. Aqueous ammonia would be stored in amounts above the threshold quantity during the final stages of construction, initial start-up, and operations phases. Transport of hazardous materials during power plant operation includes delivery of aqueous ammonia and removal of wastes. During operation, the aqueous ammonia transporter would be required to obtain a Hazardous Material Transportation License in accordance with California Vehicle Code Section 32105 and would be required to follow appropriate safety procedures and routes.
- Cultural impacts can be severe depending on the power plant siting; however, because natural gas power plants require substantially fewer acres per MW of power generated, impacts to cultural resources would be expected to be fewer than with solar facilities.
- Power plant siting may result in the permanent conversion of designated farmland to non-agricultural uses. However, because natural gas power plants require substantially fewer acres per MW of power generated, impacts to designated farmlands would be expected to be less than with solar facilities.
- Visual impacts may occur with natural gas power plants because they introduce large structures with industrial character. The most prominent structures are frequently the cooling towers, which may reach 100 feet tall, and the power plant stacks, which may reach over 100 feet tall. Visible plumes from the cooling tower would also potentially occur.

Rationale for Elimination

Although natural gas generation is clearly a viable technology, it is not a renewable technology, so it would not attain the objective of generating renewable power meeting California's renewable energy needs. The air quality impacts of gas-fired plants include greenhouse gases and are one major reason that California's RPS was developed. Therefore, this alternative is not considered in detail as an alternative to the RSEP project and is not analyzed further in this SA/EIS.

Coal Generation

Coal-fired electric generating plants are the cornerstone of America's electric power generation system. Traditional coal-fired plants generate large amounts of greenhouse gases. New clean coal technology includes a variety of energy processes that reduce air emissions and other pollutants from coal-burning power plants. The Clean Coal Power Initiative is providing government co-financing for new coal technologies that help utilities meet the Clear Skies Initiative to cut sulfur, nitrogen, and mercury pollutants by nearly 70% by 2018. The Clean Coal Power Initiative is now focusing on developing projects that use carbon sequestration technologies and/or beneficial reuse of carbon dioxide (DOE 2008). However, these technologies are not yet in use.

In 2006, approximately 15.7% of the energy used in California came from coal fired sources; 38% of this was generated in state, and 62% was imported (CEC 2007). The in-state coal-fired generation includes electricity generated from out-of-state, coal-fired power plants owned by and reported by California utilities (CEC 2007). In 2006, California enacted Senate Bill 1368 (Perata, Chapter 598, Statutes of 2006), which prohibits utilities from making long-term commitments for electricity generated from plants that create more carbon dioxide (CO₂) than clean-burning natural gas plants (CEC 2007).

Environmental Assessment

Coal-fired power plants may also result in numerous adverse environmental impacts such as the following.

- Overall, air quality impacts would increase because coal-fired power plants contribute carbon dioxide, sulfur dioxide, nitrogen oxides, mercury, and fly ash (USEPA 2008a). Mining, cleaning, and transporting coal to the power plants generates additional emissions. Average per megawatt hour emissions of a coal-fired power plant are 2,249 pounds of carbon dioxide, 13 pounds of sulfur dioxide and six pounds of nitrogen oxides (USEPA 2008a). Net increases in greenhouse gas emissions due to coal-firing in conventional power plants would be significant.
- Health risks associated with power plants have also been documented, including problems associated with exposure to fine particle pollution or soot, an increase in asthma, and an increase in non-fatal heart attacks.
- Large quantities of water are generally required to produce steam and for cooling. When coal-fired power plants use water from a lake or river, fish or other aquatic life can be adversely impacted (USEPA 2008).

Rationale for Elimination

Although coal generation is a viable technology, it is not a renewable technology, so it would not attain the objective of generating renewable power meeting California's renewable energy needs. Existing technology for coal-fired plants results in high greenhouse gas emissions. Therefore, coal generation was eliminated from detailed analysis and is not considered further in this SA/DEIS.

Nuclear Energy

Due to environmental and safety concerns, California law currently prohibits the construction of new nuclear power plants in the state until the California Energy Commission finds that the federal government has approved and there exists a demonstrated technology for the permanent disposal of spent fuel from these facilities (CEC 2006). In June 1976, California enacted legislation directing the Energy Commission to perform an independent investigation of the nuclear fuel cycle. This investigation was to assess whether the technology to reprocess nuclear fuel rods or to permanently dispose of high-level nuclear waste had been demonstrated and approved and was operational (Public Resources Code 25524.1 (a) (1), 25524.1 (b), and 25524.2 (a)). After extensive public hearings, the Energy Commission determined that it could not make the requisite affirmative findings concerning either reprocessing of nuclear fuel or disposal of high-level waste as documented in the *Status of Nuclear Fuel Reprocessing, Spent Fuel Storage and High-level Waste Disposal*, Energy Commission publication P102-78-001 (January 1978.) As a result, the development of new nuclear energy facilities in California was prohibited by law.

It has been more than 25 years since the last comprehensive Energy Commission assessment of nuclear power issues. The *Nuclear Power in California: 2007 Status Report* (October 2007) provides a detailed description of the current nuclear waste issues and their implications for California. This was prepared as part of the development of the Energy Commission's *2007 Integrated Energy Policy Report* (CEC 2007).

Rationale for Elimination

The permitting of new nuclear facilities in California is currently illegal, so this technology is infeasible and is not considered further in this SA/EIS.

Conservation and Demand-Side Management

Conservation and demand-side management consist of a variety of approaches to reduction of electricity use, including energy efficiency and conservation, building and appliance standards, and load management and fuel substitution. In 2005 the Energy Commission and CPUC's Energy Action Plan II declared cost effective energy efficiency as the resource of first choice for meeting California's energy needs. The Energy Commission noted that energy efficiency has helped flatten the state's per capita electricity use and saved consumers more than \$56 billion since 1978 (CPUC 2008). The investor-owned utilities' 2006-2008 efficiency portfolio marks the single-largest energy efficiency campaign in U.S. history, with a \$2 billion investment by California's energy ratepayers (CPUC 2008). However, with population growth, increasing demand for energy, and the need to reduce greenhouse gases, there is a greater need for energy efficiency.

The CPUC, with support from the Governor's Office, the Energy Commission, and the California Air Resources Board, among others, adopted the *California Long-Term Energy Efficiency Strategy Plan for 2009 to 2020* (CPUC 2008). The plan is a framework for all sectors in California including industry, agriculture, large and small businesses, and households. Major goals of the plan include:

- All new residential construction will be zero net energy by 2020;
- All new commercial construction will be zero net energy by 2030;
- Heating, ventilation, and air conditioning industries will be re-shaped to deliver maximum performance systems;
- Eligible low-income customers will be able to participate in the Low Income Energy Efficiency program and will be provided with cost-effective energy efficiency measures in their residences by 2020.

Rationale for Elimination

Conservation and demand-side management are important for California's energy future and cost effective energy efficiency is considered as the resource of first choice for meeting California's energy needs. However, with population growth and increasing demand for energy, conservation and demand-management alone are not sufficient to address all of California's energy needs. Additionally, it will not provide the renewable energy required to meet the California Renewable Portfolio Standard requirements, so technologies, like solar thermal generation, would be required. Therefore, they are not analyzed in detail in this SA/EIS as an alternative to the RSEP project.

CONCLUSIONS OF ALTERNATIVES ANALYSIS

In this analysis of the RSEP project, 28 alternatives to the proposed RSEP project were developed and evaluated. These include a reduced acreage alternative at the RSEP site, no action/no project alternatives, 12 alternative sites, solar and renewable technologies, generation technologies using different fuels, and conservation/demand-side management.

Of the 28 alternatives, four alternatives were determined to be reasonable by the Bureau of Land Management and Western Area Power Administration and feasible by the Energy Commission and have the potential to result in reduced impacts in comparison with the proposed project: the Reduced Acreage Alternative, the North of Desert Center Alternative, the SR 62/Rice Valley Road Transmission Line Alternative, and the No Project/No Action Alternative. CEC Staff have determined that the No Project/No Action Alternative is not superior to the proposed project because it would likely delay development of renewable resources or shift renewable development to other similar areas, and would lead to increased operation of existing power plants that use non-renewable technologies.

The Reduced Acreage Alternative, North of Desert Center Alternative and SR 62/Rice Valley Road Transmission Line Alternative would reduce impacts in comparison to the proposed project. The Reduced Acreage Alternative would be 8% smaller in size and would provide a relatively minor reduction in impacts to cultural resources on the historic Rice Army Airfield site and to biological resources. The benefits of reducing impacts may be outweighed by efficiency losses.

The North of Desert Center Alternative would eliminate all use of the historic Rice Army Airfield, which is also habitat for desert tortoise. Additionally, this alternative on mostly fallow land would avoid impacts to wildlife movement, alteration of ephemeral streams,

and alteration of sand movement. With mitigation, the operation of a private airfield servicing the nearby Chuckwalla Valley Raceway is unlikely to affect the feasibility of the alternative site. However, construction traffic at the North of Desert Center site could result in significant cumulative impacts to existing roadway level of service.

The SR 62/Rice Valley Road Transmission Line Alternative would eliminate the need for a new access road and therefore would reduce impacts to desert habitat caused by creation of a new 5.4-mile access road across undisturbed BLM land. However, the new line would traverse Camp Rice, a World War II Desert Training Center site. Its proximity to SR 62 and the California Aqueduct could affect the viewshed and increase the potential for bird collisions.

The eleven other alternative sites (Cadiz, McCoy, Agricultural Lands, Blythe Mesa, Broadwell Lake, Gabrych, Garlock Road, Manix, Mesquite Lake, Siberia East, and South of Hwy 98) would not substantially reduce impacts and the feasibility of developing projects at these locations is reduced because of size, shape and ownership limitations.

Alternative solar thermal technologies (Stirling dish, solar parabolic trough and linear Fresnel) are also evaluated. As compared with the proposed solar power tower technology, these technologies would not substantially change the severity of visual impacts, biological resources impacts and cultural resource impacts, though land requirements vary among the technologies. Distributed generation solar photovoltaic facilities (i.e., photovoltaic panels placed on surfaces such as rooftops and parking lots) would likewise require extensive acreage, although they would minimize the need for undisturbed open space. However, increased deployment of distributed solar photovoltaic technology faces challenges in manufacturing capacity, cost, and policy implementation.

Other generation technologies (wind, geothermal, biomass, tidal, wave, natural gas, and nuclear) are also examined as possible alternatives to the project. These technologies would either be infeasible at the scale of the Rice Solar Energy Project, or they would create their own significant adverse impacts in other locations. For example, a natural gas plant would use substantially less land and avoid cultural and biological resources impacts, but it would contribute to greenhouse gas emissions and would not meet the project's renewable generation objective. Construction of new nuclear power plants is currently prohibited under California law.

Conservation and demand side management programs would likely not meet the state's growing electricity needs that would be served by the Rice Solar Energy Project. In addition, these programs would not provide the renewable energy required to meet the California Renewable Portfolio Standard (RPS) requirements.

CUMULATIVE SCENARIO

Testimony of Suzanne Phinney, D. Env

CUMULATIVE SCENARIO

INTRODUCTION

Preparation of a cumulative impact analysis is required under both CEQA and NEPA. “Cumulative impact” is the impact on the environment which results from the incremental impact of the Proposed Project when considered with other past, present, and reasonably foreseeable future actions regardless of which agency (federal or non-federal) or person undertakes such other actions (40 CFR §1508.7).

The Rice Solar Energy Project is proposed to be sited on private lands and is subject to CEQA review. A portion of the proposed generation tie line would traverse land managed by the Bureau of Land Management (BLM). The project would interconnect with a Western Area Power Administration (WAPA) transmission line and would require telecommunication from RSEP to the new substation and then to a Western substation. Under CEQA Guidelines, “a cumulative impact consists of an impact which is created as a result of the combination of the project evaluated in the EIR together with other projects causing related impacts” (14 Cal Code Regs §15130(a)(1)). Cumulative impacts must be addressed if the incremental effect of a project, combined with the effects of other projects is “cumulatively considerable” (14 Cal Code Regs §15130(a)). Such incremental effects are to be “viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects” (14 Cal Code Regs §15164(b)(1)). Together, these projects comprise the cumulative scenario which forms the basis of the cumulative impact analysis.

CEQA also states that both the severity of impacts and the likelihood of their occurrence are to be reflected in the discussion, “but the discussion need not provide as great detail as is provided for the effects attributable to the project alone. The discussion of cumulative impacts shall be guided by standards of practicality and reasonableness, and shall focus on the cumulative impact to which the identified other projects contribute rather than the attributes of other projects which do not contribute to the cumulative impact” (14 Cal Code Regs §15130(b)).

NEPA states that cumulative effects can result from individually minor but collectively significant actions taking place over a period of time” (40 CFR §1508.7). Under NEPA, both context and intensity are considered. When considering intensity of an effect, we consider “[w]hether the action is related to other actions with individually minor but cumulatively significant impacts. Significance cannot be avoided by terming an action temporary or by breaking it down into small component parts.” 40 CFR §1508.27(b)(7).

The intensity, or severity, of the cumulative effects should consider the magnitude, geographic extent, duration and frequency of the effects (CEQ, 1997). The magnitude of the effect reflects the relative size or amount of the effect; the geographic extent

considers how widespread the effect may be; and the duration and frequency refer to whether the effect is a one-time event, intermittent, or chronic (CEQ, 1997).

RENEWABLE RESOURCES IN CALIFORNIA

A large number of renewable projects have been proposed on BLM land, State land, and private land in California. As of July 2010, there were 183 solar projects, 147 wind projects and 17 geothermal projects in various stages of the environmental review process or under construction in California (CEC 2010). Some of the solar, wind, and geothermal development applications have requested use of BLM land, including approximately one million acres of the California desert. State and private lands have also been targeted for renewable solar and wind projects.

A number of existing policies and incentives encourage renewable energy development. These incentives lead to a greater number of renewable energy proposals. Example of incentives for developers to propose renewable energy projects on private and public lands in California, include the following:

- U.S. Treasury Department's Payments for Specified Energy Property in Lieu of Tax Credits under §1603 of the American Recovery and Reinvestment Act of 2009 (Public Law 111-5) - Offers a grant (in lieu of investment tax credit) to receive funding for 30% of their total capital cost at such time as a project achieves commercial operation (currently applies to projects that begin construction by December 31, 2010 and begin commercial operation before January 1, 2017).
- U.S. Department of Energy (DOE) Loan Guarantee Program pursuant to §1703 of Title XVII of the Energy Policy Act of 2005 - Offers a loan guarantee that is also a low interest loan to finance up to 80% of the capital cost at an interest rate much lower than conventional financing. The lower interest rate can reduce the cost of financing and the gross project cost on the order of several hundred million dollars over the life of the project, depending on the capital cost of the project.

The large renewable projects now described in applications to the BLM and on private land are competing for utility Power Purchase Agreements, which will allow utilities to meet state-required Renewable Portfolio Standards. Not all projects will complete the environmental review, and not all projects will be funded and constructed. It is unlikely that all proposed projects will be constructed for the following reasons:

- Not all developers will develop the detailed information necessary to meet BLM and Energy Commission standards. Some of the solar projects with pending applications are proposing generation technologies that have not been implemented at large scales. As a result, preparing complete and detailed plans of development (PODs) is difficult, and completing the required NEPA and CEQA documents is especially time-consuming and costly.
- As part of approval by the appropriate Lead Agency under CEQA and/or NEPA (generally the Energy Commission and/or BLM), all regulatory permits must be obtained by the applicant or the prescriptions required by the regulatory authorities incorporated into the Lead Agency's license, permit or right-of-way grant. The large size of these projects may result in permitting challenges related to endangered species, mitigation measures or requirements, and other issues.

- Also after project approval, construction financing must be obtained (if it has not been obtained earlier in the process). The availability of financing will be dependent on the status of competing projects, the laws and regulations related to renewable project investment, the ability to qualify for renewable energy incentives offered by the federal government and the time required for obtaining permits.

DEFINITION OF THE CUMULATIVE PROJECT SCENARIO

Cumulative impacts analysis is intended to highlight past actions that are closely related either in time or location to the project being considered, catalogue past projects and discuss how they have harmed the environment, and discuss past actions even if they were undertaken by another agency or another person. Most of the projects proposed in California have, are, or will be required to undergo their own independent environmental review under either CEQA or NEPA.

Under CEQA, there are two acceptable and commonly used methodologies for establishing the cumulative impact setting or scenario: the “list approach” and the “projections approach.” The first approach would use a “list of past, present, and probable future projects producing related or cumulative impacts.” 14 Cal Code Regs §15130(b)(1)(A). The second approach would use a “summary of projections contained in an adopted general plan or related planning document, or in a prior environmental document which has been adopted or certified, which described or evaluated regional or area wide conditions contributing to the cumulative impact.” (14 Cal Code Regs §15130(b)(1)(B)). This SA/DEIS uses the “list approach” for purposes of state law to provide a tangible understanding and context for analyzing the potential cumulative effects of a Project.

In order to provide a basis for cumulative analysis for each discipline, this section provides information on other projects in both maps and tables. The Energy Commission and the BLM have identified the California desert as the largest area within which cumulative effects should be assessed for all disciplines, as shown in two maps and accompanying tables. However, within the desert region, the specific area of cumulative effect varies by resource. For this reason, each discipline has identified the geographic scope for the discipline’s analysis of cumulative impacts. Information on projects within the California desert is provided in the following tables and figures:

- Cumulative Impacts Table 1A lists renewable energy projects on BLM land in the California Desert District as defined by BLM.
- Cumulative Impacts Table 1B lists renewable energy projects on State and private lands in California .
- Cumulative Impacts Table 2 lists the existing projects in the Rice Valley area as well as existing projects in the eastern Riverside County area.
- Cumulative Impacts Table 3 lists future foreseeable projects in the Rice Valley area as well as future foreseeable projects in the eastern Riverside County area.
- Cumulative Impacts Figure 1 shows the general location of BLM lease applications within the California Desert District.

- Cumulative Impacts Figure 2 shows the location of existing and future foreseeable projects within the Rice Valley area and eastern Riverside County area.

All tables and figures are presented at the end of this section.

APPROACH TO CUMULATIVE IMPACT ANALYSIS

This SA/DEIS evaluates cumulative impacts within the analysis of each resource area, following these steps:

1. Define the geographic scope of cumulative impact analysis for each discipline, based on the potential area within which impacts of the Rice Solar Energy Project could combine with those of other projects.
2. Evaluate the effects of the Rice Solar Energy Project in combination with past and present (existing) projects within the area of geographic effect defined for each discipline.
3. Evaluate the effects of the Rice Solar Energy Project with foreseeable future projects that occur within the area of geographic effect defined for each discipline.

Each of these steps is described below.

Geographic Scope of Cumulative Analysis

The area of cumulative effect varies by resource. For example, air quality impacts tend to disperse over a large area, while traffic impacts are typically more localized. For this reason, the geographic scope for the analysis of cumulative impacts must be identified for each resource area.

The analysis of cumulative effects considers a number of variables including geographic (spatial) limits, time (temporal) limits, and the characteristics of the resource being evaluated. The geographic scope of each analysis is based on the topography surrounding the Rice Solar Energy Project and the natural boundaries of the resource affected, rather than jurisdictional boundaries. The geographic scope of cumulative effects will often extend beyond the scope of the direct effects, but not beyond the scope of the direct and indirect effects of the proposed action and alternatives.

In addition, each project in a region will have its own implementation schedule, which may or may not coincide or overlap with the Rice Solar Energy Project schedule. This is a consideration for short-term impacts from the Rice Solar Energy Project. However, to be conservative, the cumulative analysis assumes that all projects in the cumulative scenario are built and operating during the operating lifetime of the Rice Solar Energy Project.

Project Effects in Combination with Future Foreseeable Projects

Each discipline evaluates the impacts of the proposed project in light of the current baseline - the past, present (existing) and future projects near the Rice Solar Energy Project plant site. Cumulative Impacts Table 2 lists the existing projects within a 15-20 mile radius around the project site, encompassing the Rice Valley area. In addition, the

cumulative boundary was extended to include other renewable energy projects being sited in eastern Riverside County along the I-10 corridor. This extended boundary does not exceed a 40 mile radius around the proposed Rice project. Cumulative Impacts Table 3 lists the future/foreseeable projects in the Rice Valley area as well as eastern Riverside County. Both tables indicate project name, type, location, and status. Cumulative Impacts Figure 2 shows the locations of the existing and future/foreseeable projects in the Rice Valley area as well as the eastern Riverside County area.

Reasonably foreseeable projects that could contribute to the cumulative effects scenario depend on the extent of resource effects, but could include projects in the immediate Rice Solar Energy Project area as well as other large renewable projects in the California desert region. These projects are illustrated in Cumulative Impacts Table 1A and 1B and Cumulative Impacts Figures 1 and 2. As shown in the map and table, there are several projects in the region around the Rice Solar Energy Project whose impacts could combine with those of the proposed project. As shown on Cumulative Impacts Figure 1 and in Table 1, solar and wind development applications for use of BLM land have been submitted for approximately one million acres of the California Desert Conservation Area. Additional BLM land in Nevada and Arizona also has applications for solar and wind projects.

This data is presented for consideration within each discipline.

Table 1B. Renewable Energy Projects on State and Private Lands in California		
Project	Location	Status
Solar Projects		
3 MW solar PV energy generating facility	San Bernardino County, Newberry Springs	MND published for public review
Abengoa Mojave Solar Project (250 MW solar thermal)	San Bernardino County, Harper Lake	Under environmental review
Antelope Valley Solar Ranch One (230 MW Solar PV)	Los Angeles and Kern Counties	Under environmental review
AV Solar Ranch One (230 MW solar PV)	Antelope Valley, Los Angeles County	Under environmental review
Beacon Solar Energy Project (250 MW Solar Thermal)	Kern County	Application for Certification approved by CEC
Bethel Solar Hybrid Power Plant (49.4 MW hybrid solar thermal and biomass)	Seeley, Imperial County	Under environmental review
Blythe Airport Solar 1 Project (100 MW solar PV)	Blythe, California	MND published for public review
Borrego Solar Farm (45 MW Solar PV)	San Diego County	Under environmental review
California Valley Solar Ranch (SunPower) (250 MW solar PV)	Carrizo Valley, San Luis Obispo County	Under environmental review
First Solar's Blythe (21 MW solar PV)	Blythe, California	Under construction
GE Energy LLC (40 MW Solar PV)	Kern County	Under environmental review
LADWP and OptiSolar Power Plant (68 MW solar PV)	Imperial County, SR 111	Under environmental review
LADWP Solar Project (10 MW Solar PV)	Kern County	Under environmental review
Lucerne Valley Solar (50 MW solar PV)	San Bernardino	Under environmental review
Mt. Signal Solar Power Station (49.4 MW hybrid solar thermal and biomass)	8 miles southwest of El Centro, Imperial County	Under environmental review
Palmdale Hybrid Power Project Unit 1 (50 MW solar thermal, part of a hybrid project)	City of Palmdale	Under environmental review
Rice Solar Energy Project (150 MW solar thermal)	Riverside County, north of Blythe	Under environmental review
Rosamond Solar Array (155 MW Solar PV)	Kern County	Under environmental review
San Joaquin Solar 1 and 2 (107 MW Solar hybrid)	Fresno	Under environmental review
Solargen Panoche Valley Solar Farm (400 MW Solar PV)	San Benito County	EIR in progress
Topaz Solar Farm (First Solar) (550 MW solar PV)	Carrizo Valley, San Luis Obispo County	Under environmental review
Willow Springs Solar Array (160 MW Solar PV)	Kern County	Under environmental review
Wind Projects		
AES Daggett Ridge (84 MW)	San Bernardino	EIS in progress

Table 1B. Renewable Energy Projects on State and Private Lands in California		
Project	Location	Status
Alta-Oak Creek Mojave Project (up to 800 MW)	Kern County, west of Mojave	Under environmental review
Granite Wind, LLC (81 MW)	San Bernardino	EIR/EIS in progress
Hatchet Ridge Wind Project	Shasta County, Burney	Under construction
Iberdrola Tule Wind (200 MW)	San Diego County, McCain Valley	EIR/EIS in progress
Lompoc Wind Energy Project	Lompoc, Santa Barbara County	Approved
Pacific Wind (Iberdrola)	McCain Valley, San Diego County	Under environmental review
PdV Wind Energy Project (up to 300 MW)	Kern County, Tehachapi Mountains	Approved
Solano Wind Project Phase 3 (up to 128 MW)	Montezuma Hills, Solano County	Under environmental review
TelStar Energies, LLC (300 MW)	Ocotillo Wells, Imperial County	Under environmental review
Geothermal Projects		
Buckeye Development Project	Geyserville, Sonoma	Under environmental review

Table 2. Existing Projects in the Rice Valley area and Eastern Riverside County

Project Name;	Agency ID	Location	Ownership	Status	Acres	Project Description
Existing Projects in the Rice Valley area within 15-20 miles of proposed project						
1	Iron Mountain Pumping Plant	Iron Mountain Pump Plant Road, ~18 miles northwest of Rice project	Metropolitan Water District of Southern California	Existing	N/A	Iron Mountain Pump Plant is part of the Metropolitan Water District of Southern California's facilities and houses the pumping plant, holding ponds, a small residential area and a portion of the Colorado River aqueduct itself. Ongoing Operation and Maintenance activities occur frequently and will continue throughout the life of the Pump Plant.
2	Iron Mountain Pump Plant Airport - Private	Iron Mountain Pump Plant Road, ~18 miles northwest of Rice project	Metropolitan Water District of Southern California	Existing	N/A	Privately owned and operating airport 18 miles northwest of the proposed Rice Solar Energy project.
3	Metropolitan Water District 230-kV Transmission Line	Riverside County, San Bernardino County, ~18 miles west of the proposed Rice project	Metropolitan Water District	Existing	N/A	Metropolitan Water District's 230-kV line running in a north-south direction from Camino Substation near Needles Freeway (Hwy 40) in San Bernardino County south to Eagle Mountain Substation in Riverside County.

Table 2. Existing Projects in the Rice Valley area and Eastern Riverside County

ID #	Project Name; Agency ID	Location	Ownership	Status	Acres	Project Description
4	Iron Mountain Substation	San Bernardino County, ~18 miles northwest of the proposed project	Metropolitan Water District	Existing	N/A	Metropolitan Water District's Iron Mountain Substation located approximately 18 miles northwest of the proposed Rice Solar Energy Project.
5	Western Area Power Administration 161-kV Transmission Lines (2)	Two existing lines in eastern Riverside County, ~12 and ~20 miles east of proposed project.	Western Area Power Administration (WAPA)	Existing	N/A	WAPA's two 161-kV transmission lines running in a north-south direction east of proposed Rice Solar Energy Project, both terminating near CA/AZ border near Lake Havasu.
6	Rice Valley Grazing Allotment	Rice Valley, surrounding Rice Solar Energy Project to east, south and west.	BLM	Existing	74,740	A 10-year grazing lease on the Rice Valley Grazing Allotment authorizes sheep grazing on public land. The allotment boundaries form a U-shape parcel surrounding the proposed project site. The eastern boundary begins at approximately 2 miles east of the site and extends for ~2 miles east; the western boundary begins at approximately 2 miles west of the site and extends ~4 miles west. The southern boundary begins ~1 mile south of the site and extends ~10 miles south.
7	Arizona-California Railroad	Runs from Cadiz, Ca to Parker, Az. A portion parallels State Route 62, immediately north of proposed Rice project.	RailAmerica	Existing	N/A	The Arizona-California railroad operates nearly 300 miles of rail encompassing 190 miles of rail from Cadiz, Ca to Matthie, Az, 57 miles from Matthie, Az to Pheonix, Az and a 50 mile branch extending from Rice, Ca to Ripley, Ca.
8	Colorado River Aqueduct	Runs parallel to State Route 62, immediately north of proposed Rice project.	Metropolitan Water District of Southern California	Existing	N/A	The aqueduct carries water 242 miles, from Lake Havasu, on the Colorado River, to Lake Matthews in western Riverside County.

Table 2. Existing Projects in the Rice Valley area and Eastern Riverside County

ID #	Project Name; Agency ID	Location	Ownership	Status	Acres	Project Description
9	West-wide Section 368 Energy Corridors	Riverside County	BLM, DOE, U.S. Forest Service	Approved by BLM and U.S. Forest Service	N/A	Designation of corridors on federal land in the 11 western states, including California, for oil, gas, and hydrogen pipelines and electricity transmission and distribution facilities (energy corridors). One of the corridors runs along the southern portion of Riverside County.
10	Recreational Opportunities	Eastern Riverside County	BLM	Existing	N/A	BLM has numerous recreational opportunities on lands in eastern Riverside County and bordering eastern San Bernardino County, including Rice Valley Wilderness Area, Palen/McCoy Wilderness Area, the Turtle Mountains Wilderness Trail, Blythe-Vidal Old Road Trail, and Midland Long-Term Visitor Area.

Additional Existing Projects Outside 15-20 mile Boundary in Eastern Riverside County

11	Interstate 10	Linear project running from Santa Monica to Blythe (in California)	Caltrans	Existing	N/A	Interstate 10 (I-10) is a major east-west route for trucks delivering goods to and from California. It is a four lane divided highway in the Blythe region.
12	Eagle Mountain Pumping Plant	Eagle Mountain Road, west of Desert Center	Metropolitan Water District of Southern California	Existing	N/A	144 ft. pumping plant that is part of the Metropolitan Water District of Southern California's facilities located approximately 40 miles southwest of the proposed Rice project.
13	Blythe Energy Project	City of Blythe, north of I-10, 7 miles west of the CA/AZ border	Blythe Energy, LLC	Existing	76	520 MW combined-cycle natural gas-fired electric-generating facility. Project is connected to the Buck Substation owned by WAPA.
14	Kaiser Mine	Eagle Mountain, north of Desert Center	Kaiser Ventures, Inc.	Mining activities stopped in 1983.	N/A	Kaiser Steel mined iron ore at Kaiser Mine in Eagle Mountain and provided much of the Pacific Coast steel in the 1950s. Mining project also included the Eagle Mountain Railroad, 51 miles long. Imported steel captured market share in the 1960s and 1970s and primary steelmaking closed in the 1980s.
15	Devers-Palo Verde Transmission Line	From the Midpoint Substation to Devers Substation	Southern California Edison	Existing	N/A	Existing 500 kV transmission line parallel to I-10 from Midpoint Substation, approximately 10 miles southwest of Blythe, to the SCE Devers Substation, near Palm Springs.

Table 3. Future Foreseeable Projects in the Rice Valley area and Eastern Riverside County

Project Name; ID #	Agency ID	Location	Ownership	Status	Acres	Project Description
Future Foreseeable Projects in the Rice Valley area within 15-20 miles of proposed project						
A	Three Colorado River Aqueduct Rehabilitation Projects	Iron Mountain Pump Plant, ~18 miles northwest of proposed Rice project	Metropolitan Water District of Southern California	Under Construction	N/A	Metropolitan Water District of Southern California proposes to repair the delivery line expansion joints at the Iron Mountain Pumping Plant, located approximately 18 miles northwest of the proposed project. The work is scheduled to be complete February of 2011.
B	Ward Valley, Leopold Companies, Inc	San Bernardino County, ~5 miles northwest of proposed Rice project in the Ward Valley	Leopold Companies, Inc	Plan of Development in to Needles BLM	8,000	750 MW solar thermal power plant proposed in the Ward Valley approximately 5 miles northwest of the proposed Rice Solar Energy project.
Additional Future Foreseeable Projects Outside 15-20 mile Boundary in Eastern Riverside County						
C	Colorado River Substation	1.5 miles south of Interstate 10 and 4.75 miles east of Wileys Well Road	SCE		140	Expand the 500 kV switchyard, previously approved as part of the DPV2 CPCN on approximately 45 acres of land, into a full 500/220 kV substation on approximately 90 acres of land.
D	Desert Quartzite	South of I-10, 8 miles southwest of Blythe	First Solar (previously OptiSolar)	POD in to BLM	7,724	600 MW solar photovoltaic project located on 7,724 acres. Adjacent to DPV transmission line and SCE Colorado Substation. Approximately 27 AF would be used during construction and 3.8 AFY during operation.
E	Killbeck	26 miles northwest of proposed Rice project	Boulevard Associates	Plan of Development in to Needles BLM	12,046	1,000 MW solar thermal power plant located 26 miles northwest of proposed Rice project.
F	Cadiz Lake	26 miles west of proposed Rice project	Boulevard Associates	Plan of Development in to Needles BLM	35,639	1,000 MW solar thermal power plant located 26 miles west of proposed Rice project.

Table 3. Future Foreseeable Projects in the Rice Valley area and Eastern Riverside County

Project Name; ID #	Agency ID	Location	Ownership	Status	Acres	Project Description
G	Desert Sunlight	35 miles southwest of proposed Rice project	First Solar	Undergoing environmental review	5,128	550 MW solar photovoltaic project located 6 miles north of Desert Center in eastern Riverside County. The project footprint is 4,410 acres and the BLM ROW application is for 5,128 acres. Project would tie into the SCE Red Bluff substation. Approximately water usage is; 27 AFY of during construction and 3.8 AFY during operation.
H	EnXco 1	36 miles southwest of proposed Rice project	EnXco Development LLC	Plan of Development in to Palm Springs BLM	1,327	300 MW solar thermal power plant located north of Desert Center.
I	Chuckwalla Solar I	35 miles southwest of proposed Rice project, 1 mile north of Desert Center	Chuckwalla Solar I, LLC	Plan of Development submitted to BLM	4,099	200 MW solar photovoltaic project on 4,099 acres of land. Project would be developed in several phases and would tap into an existing SCE 161-kV transmission line crossing the site.
J	Palen Solar Power Project	33 miles southwest of proposed Rice project, 10 miles east of Desert Center	Solar Millennium LLC/Chevron Energy	Undergoing environmental review, construction to begin end of 2010.	5,213	500 MW solar trough project on 5,213 acres. Facility would consist of two 250 MW plants. Approximately 3,870 acres would be disturbed. Project would include interconnection to the SCE Red Bluff Substation. Project would use 300 AFY of water.
K	Genesis Solar Energy Project	30 miles south of proposed Rice project, north of I-10, near Ford Dry Lake	NextEra (FPL)	Undergoing environmental review. Construction to begin at the end of 2010.	4,535	250 MW solar trough project located on 4,535 acres north of the Ford Dry Lake. Project includes six mile natural gas pipeline and a 5.5 mile gen-tie line to the Blythe Energy Center to Julian Hinds Transmission Line, and then travels east on shared transmission poles to the Colorado River Substation.
L	Blythe Solar Power Project	26 miles southeast of proposed Rice project	Solar Millennium LLC/Chevron Energy	Undergoing environmental review	9,481	1,000 MW solar trough facility on 9,481 acres
M	McCoy Project	20 miles south of proposed Rice project	EnXco development, LLC	Plan of Development in to Palm Springs BLM	20,608	250 MW solar trough project. ROW in process for monitoring water well drilling.
N	Big Maria Vista Solar Project	14 miles south of proposed Rice project	Bullfrog Green Energy	Plan of Development submitted to BLM	22,717	500 MW solar photovoltaic project, BLM ROW application is for 22,717 acres of land. Project would be built in three phases and would require 6,000 gallons of water monthly.

Table 3. Future Foreseeable Projects in the Rice Valley area and Eastern Riverside County

Project ID #	Project Name; Agency ID	Location	Ownership	Status	Acres	Project Description
O	Four Commercial Projects	Blythe, CA	Various	Approved	N/A	Four commercial projects have been approved by the Blythe Planning Department including the Agate Road Boat & RV Storage, Riverway Ranch Specific Plan, Subway Restaurant and Motel, and Agate Senior Housing Development.
P	Intake Shell	Blythe, CA		Under Construction	N/A	Reconstruction of a Shell facility located at Intake & Hobsonway. Demolition occurred in 2008, reconstruction planned for 2009-2010.
Q	Eighteen Residential Developments	Blythe, CA	Various	Approved/Under Construction	N/A	Fifteen residential development projects have been approved by the Blythe Planning Department including: Vista Palo Verde (83 Single Family Residential [SFR]), Van Weelden (184 SFR), Sonora South (43 SFR), Ranchette Estates (20 SFR), Irvine Assets (107 SFR), Chanslor Village (79 SFR), St. Joseph's Investments (69 SFR), Edgewater Lane (SFR), The Chanslor Place Phase IV (57 SFR), Cottonwood Meadows (103 Attached SFR), Palo Verde Oasis Phase IV (29 SFR). Three residential development projects have been approved and are under construction including: The Chanslor Phase II & III (78 SFR), River Estate at Hidden Beaches, Mesa Bluffs Villas (26 Attached SFR).
R	Blythe PV Project	Blythe, CA	First Solar	CPUC approved project terms of a 20 year power purchase agreement for sale of 7.5 MW, Under construction in forth quarter, 2009	200	7.5 MW solar photovoltaic project located on 200 acres. Project was constructed by First Solar and sold to NRG Energy.
S	Blythe Energy Project Transmission Line	From the Blythe Energy Project (Blythe, CA) to Devers Substation	Blythe Energy, LLC	Under construction	N/A	Transmission Line Modifications including upgrades to Buck Substation, approximately 67.4 miles of new 230 kV transmission line between Buck Substation and Julian Hinds Substation, upgrades to the Julian Hinds Substation, installation of 6.7 miles of new 230 kV transmission line between Buck Substation and SCE's DPV 500 kV transmission line.
T	Green Energy Express Transmission Line Project	70-mile transmission line from the Eagle Mountain Substation to southern California	Green Energy Express LLC	September 9, 2009, Green Energy Express LLC filed a Petition for Declaratory Order requesting that FERC approve certain rate incentives for the project	N/A	70-mile double-circuit 500 kV transmission line and new 500/230 kV substation from near the Eagle Mountain Substation (eastern Riverside County) to Southern California

Table 3. Future Foreseeable Projects in the Rice Valley area and Eastern Riverside County

Project Name; ID #	Agency ID	Location	Ownership	Status	Acres	Project Description
U	Blythe Energy Project II	Blythe, CA. Near the Blythe Airport and I-10	Blythe Energy, LLC	Approved December 2005	30 acres (located on Blythe Energy Project land)	520 MW combined-cycle power plant located entirely within the Blythe Energy Project site boundary. Blythe Energy Project II will interconnect with the Buck Substation constructed by WAPA as part of the Blythe Energy Project. Project is designed on 30 acres of a 76-acre site.
V	Eagle Mountain Pumped Storage Project	Eagle Mountain iron ore mine, north of Desert Center	Eagle Crest Energy Company	License application filed with FERC in June 2009	1,524	1,300 MW pumped storage project designed to store off-peak energy to utilize during on-peak hours. The captured off-peak energy will be used to pump water to an upper reservoir where the energy will be stored. The water will then be released to a lower reservoir through an underground electrical generating facility where the stored energy will be released back into the Southwestern grid during "high demand peak" times, primarily weekdays. Estimated water use is 8,100 AFY for the first four-year start-up period and replacement water is 1,763 AFY thereafter. 1
W	Blythe Airport Solar I Project	Blythe Airport, 31 miles south of proposed Rice Solar project	U.S. Solar	Application has been submitted to City of Blythe, City of Blythe approved the project in November, 2009	640	100 MW solar photovoltaic project located on 640 acres of Blythe airport land.
X	Red Bluff Substation	South of Desert Center	SCE		N/A	Proposed 230/500 kV Substation near Desert Center. Planned to interconnect renewable projects near Desert Center with the Devers-Palo Verde transmission line.
Y	Chuckwalla Valley Raceway	Desert Center Airport (no longer a functioning airport)	Developer Matt Johnson	Under construction, track expected to be open in mid 2010	400	Proposed 500-mile race track located on 400 acres of land that used to belong to Riverside County and was used as the Desert Center airport.

Table 3. Future Foreseeable Projects in the Rice Valley area and Eastern Riverside County

Project ID #	Project Name; Agency ID	Location	Ownership	Status	Acres	Project Description
Z	Eagle Mountain Landfill Project	Eagle Mountain, North of Desert Center	Mine Reclamation Corporation and Kaiser Eagle Mountain, Inc.	U.S. Court of Appeals for the Ninth Circuit issued its ruling regarding the EIS for the project in 11/09 and ruled that the land exchange for the project was not properly approved by the administrative agency. Kaiser's Mine and Reclamation is considering all available options.	~ 3,500	The project proposed to develop the project on a portion of the Kaiser Eagle Mountain Mine in Riverside County, California. The proposed project comprises a Class III nonhazardous municipal solid waste landfill and the renovation and repopulation of Eagle Mountain Townsite. The proposal by the proponent includes a land exchange and application for rights-of-way with the Bureau of Land Management and a Specific Plan, General Plan Amendment, Change of Zone, Development Agreement, Revised Permit to Reclamation Plan, and Tentative Tract Map with the County. The Eagle Mountain landfill project is proposed to accept up to 20,000 tons of non-hazardous solid waste per day for 50 years.
AA	Wiley Well Communication Tower (part of the Public Safety Enterprise Communication System)	East of Wileys Well Road, just south of I-10	Riverside County	Final EIR for the Public Safety Enterprise Communication System published in August 2008.	N/A	The Public Safety Enterprise Communication project is the expansion of the County of Riverside's fire and law enforcement agencies approximately 20 communication sites to provide voice and data transmission capabilities to assigned personnel in the field.
AB	Desert Southwest Transmission Line	118 miles primarily parallel to DPV	Imperial Irrigation District	Final EIR prepared 2005. Approved by the BLM in 2006.	N/A	New, approximately 118-mile 500 kV transmission line from a new substation/switching station near the Blythe Energy Project to the existing Devers Substation located approximately 10 miles north of Palm Springs, California.
AC	Mule Mountain Solar Project	South of I-10, approximately 4 miles west of Blythe	Bullfrog Green Energy	Plan of Development in to Palm Springs BLM	2,684	500 MW solar concentrating photovoltaic project located on 2,684 acres. Considering interconnection with proposed SCE Colorado Substation. Approximately 6,000 gallons of water would be required monthly.
Additional Projects Outside Cumulative Figure Boundaries						

Table 3. Future Foreseeable Projects in the Rice Valley area and Eastern Riverside County

Project Name; ID #	Agency ID	Location	Ownership	Status	Acres	Project Description
Proposed National Monument (former Catellus Lands)		Between Joshua Tree National Park and Mojave National Preserve		In December 2009, Senator Feinstein introduced bill S.2921 that would designate two new national monuments including the Mojave Trails National Monument.	941,000 acres	The proposed Mojave Trails National Monument would protect approximately 941,000 acres of federal land, including approximately 266,000 acres of the former railroad lands along historic Route 66. The BLM would be given the authority to conserve the monument lands and also to maintain existing recreational uses, including hunting, vehicular travel on open roads and trails, camping, horseback riding and rock hounding.
BLM Renewable Energy Study Areas		Northwest of Rice Solar project in San Bernardino County and along the I-10 corridor	BLM	Proposed	N/A	The DOE and BLM identified 24 tracts of land as Solar Energy Study Areas in the BLM and DOE Solar PEIS. These areas have been identified for in-depth study of solar development and may be found appropriate for designation as solar energy zones in the future.
Solar Energy projects along Arizona Border		Approximately 15 miles east of the CA/ AZ border along I-10 corridor	Various	Applications filed in to Arizona BLM field offices, application status listed as pending.	N/A	Five solar trough and solar power tower projects have been proposed along the I-10 corridor approximately 15 miles east of the CA/AZ border. The projects have been proposed on BLM administered-land in the Yuma and Kingman Field Offices and have requested use of approximately 75,000 acres.
Paradise Valley "New Town" Development		Approximately 30 miles west of Desert Center (7 miles east of the city of Coachella)	Glorious Land Company	Notice of Preparation of an EIR published in December of 2005. Still under environmental review.	6,397	Company proposed to develop a planned community as an international resort destination with residential, recreational, commercial, and institutional uses and facilities. The project is planned as a self-contained community with all public and quasi-public services provided. The project is located outside the Coachella Valley Water District (CVWD) boundaries and the applicant has entered into an agreement with the CVWD to manage artificial recharge of the Shaver's Valley groundwater. The proponent has purchased a firm water supply from Rosedale-Rio Bravo Water District in Kern County. In-kind water will be transferred to the MWD which will release water from the Colorado River Aqueduct to a 38 acre percolation pond on the project site. The MWD will deliver approximately 10,000 AFY to the percolation pond and over the long term, no net loss of groundwater in storage is anticipated.

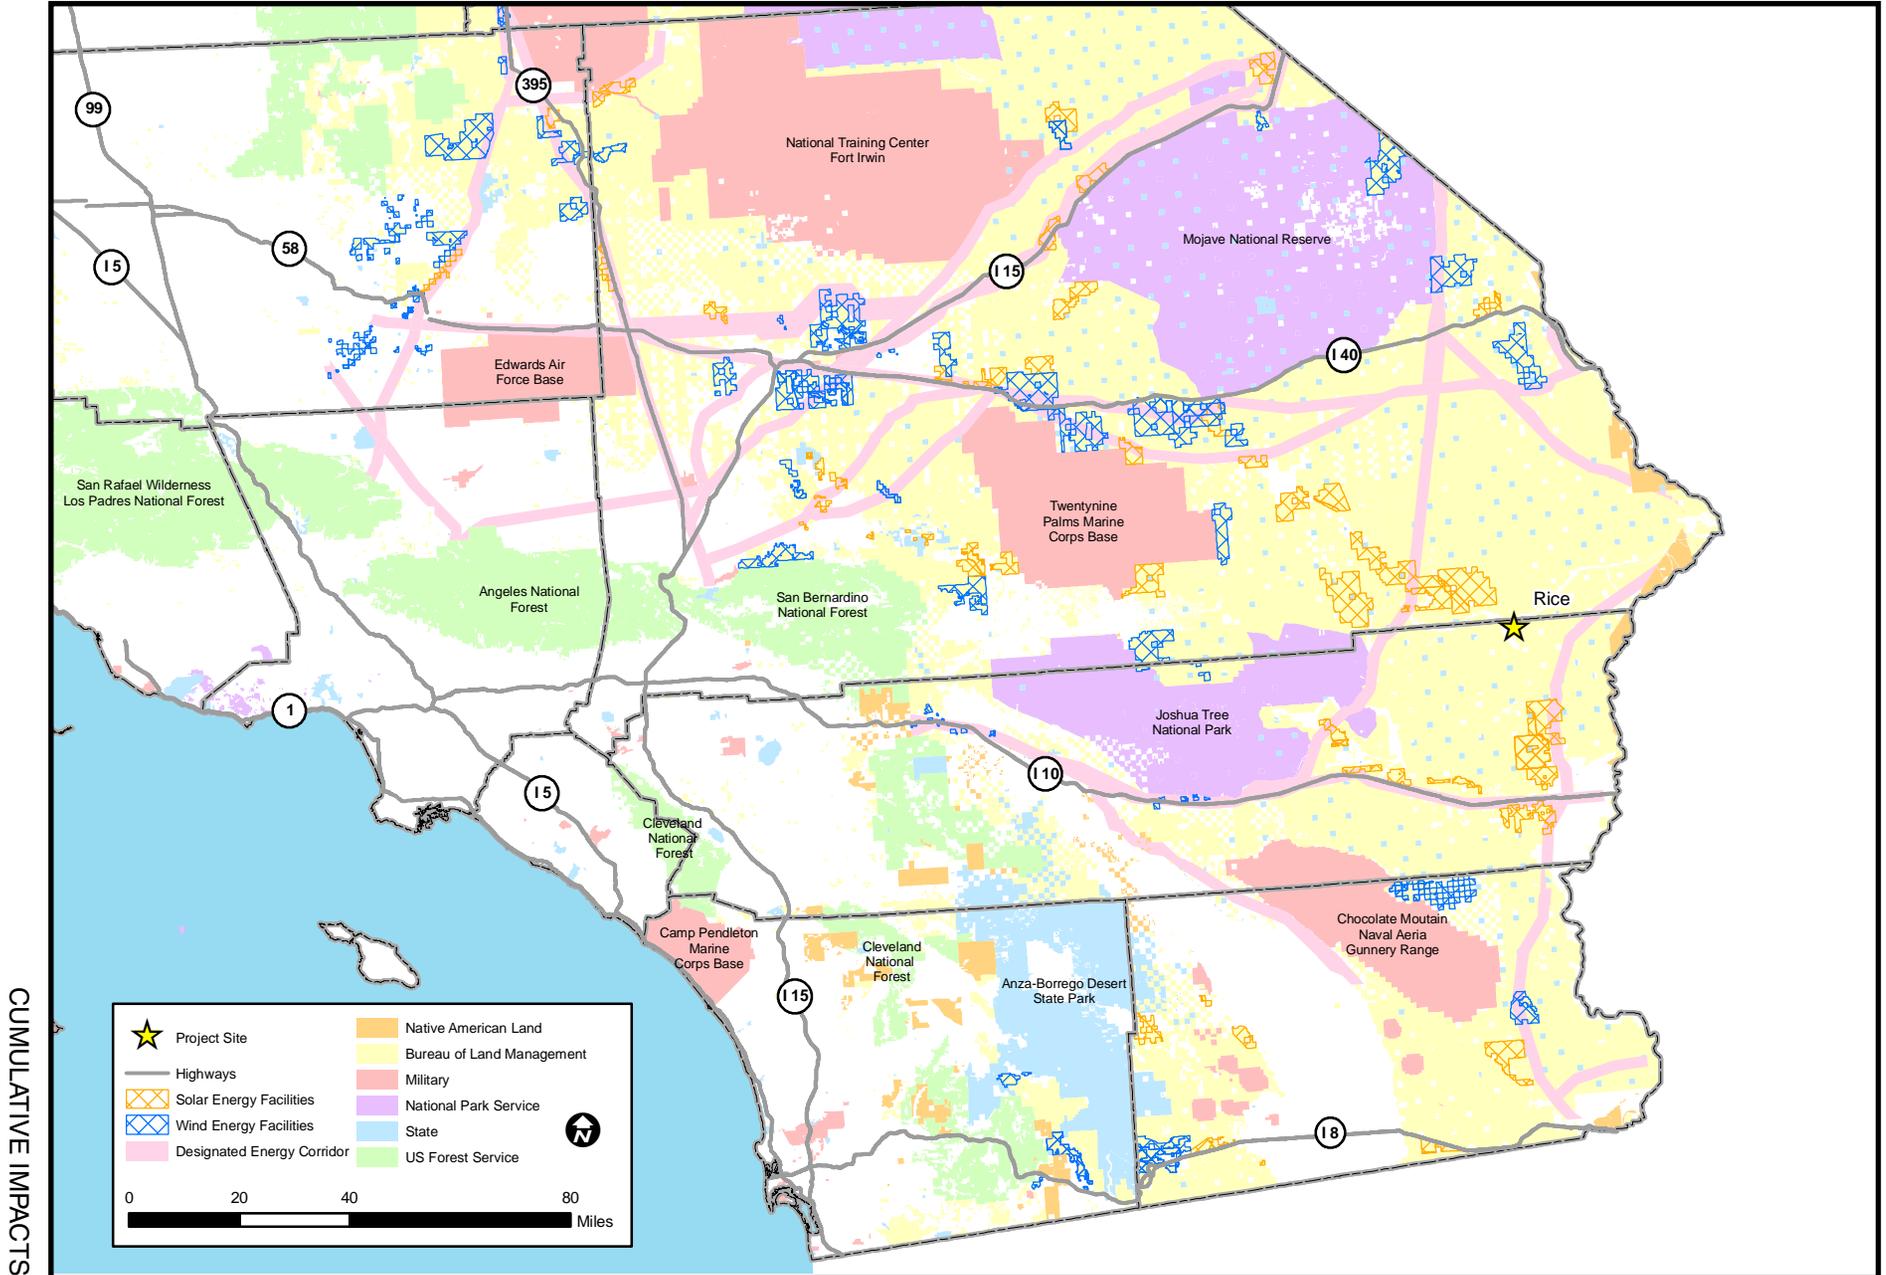

1. Water usage for the Eagle Mountain Pumped Storage Project was based on the information provided to FERC by the Eagle Crest Energy Company in the Responses to Deficiency of License Application and Additional Information Request dated October 26, 2009.

CUMULATIVE IMPACTS - FIGURE 2
 Rice Solar Energy Project - Existing and Future/Foreseeable Projects

ENVIRONMENTAL ASSESSMENT

AIR QUALITY

Testimony of Brenner Munger, Ph.D., P.E., William Walters, P.E., and Jacquelyn Leyva

SUMMARY OF CONCLUSIONS

California Energy Commission staff (hereinafter referred to as “staff”) find that with the adoption of the attached Conditions of Certification the proposed Rice Solar Energy Project (RSEP) would comply with all applicable laws, ordinances, regulations, and standards and would not result in any significant California Environmental Quality Act (CEQA) air quality impacts. These Conditions of Certification meet the Energy Commission’s responsibility to comply with CEQA and serve as recommendations for the Energy Commission to consider in its decision to avoid or reduce the severity of impacts to less than significant and assure conformance with applicable laws, ordinances, regulations and standards (LORS). The identification of relevant and reasonable mitigation measures also conforms to National Environmental Policy Act (NEPA) requirements for U.S. Bureau of Reclamation’s (BLM’s) and Western Area Power Administration’s (Western’s) analysis that can be considered in its Record of Decision.

Staff has concluded that the proposed project would not have the potential to exceed Prevention of Significant Deterioration emission threshold levels during direct source operation and the facility is not considered a major stationary source with potential to cause adverse National Environmental Policy Act air quality impacts.

The Rice Solar Energy Project would emit substantially lower greenhouse gas¹ emissions per megawatt-hour than fossil fueled generation resources in California. The Rice Solar Energy Project, as a renewable energy generation facility, is determined by rule to comply with the Greenhouse Gas Emission Performance Standard requirements of SB 1368 (Chapter 11, Greenhouse Gases Emission Performance Standard, Article 1, Section 2903 [b][1]).

INTRODUCTION

This analysis has been prepared by staff and serves as staff’s testimony in the Energy Commission’s RSEP licensing proceeding in accordance with CEQA. This analysis also serves as BLM’s and Western’s assessment of the proposed RSEP in accordance with NEPA. The analysis evaluates air quality impacts associated with the proposed RSEP’s construction, operating and decommissioning activities. Rice Solar Energy, LLC (applicant) submitted an Application for Transmission and Utility Systems and Facilities on Federal Lands to the Bureau of Land Management (BLM) on May 12, 2009 (CACA 051022) and an Application for Certification (AFC) (SR 2009a) on October 13, 2009, to construct and operate a solar power plant located in unincorporated eastern Riverside County, California, approximately fifteen miles southwest of the rural crossroads community of Vidal Junction, California. The project site is approximately 40 miles northwest of Blythe, 65 miles west of Needles, and 75 miles east of Twentynine Palms.

¹ Greenhouse gas emissions are not criteria pollutants, but they affect global climate change. In that context, staff evaluates the GHG emissions from the proposed project (Appendix Air-1), presents information on GHG emissions related to electricity generation, and describes the applicable GHG standards and requirements.

State Route 62 is immediately adjacent to the northern boundary of the proposed solar generation facility and would be the primary access during construction and operation. The applicant proposes to develop a 150-MW solar-powered electrical generation facility located within a private land holding that totals 3,324 acres, which would be subdivided to create a project parcel of 2,560 acres. Within this project parcel will be the administration buildings area, heliostat field with power block, and evaporation pond areas, (collectively, the project site or facility site) totaling 1,410 acres, that will be surrounded by a security fence.

This analysis evaluates the expected air quality impacts from the emissions of criteria air pollutants associated with the construction, salt system conditioning and operation of the Rice Solar Energy Project (RSEP or proposed project). Criteria air pollutants are defined as air contaminants for which the state and/or federal governments, per the California Clean Air Act and federal Clean Air Act, have established ambient air quality standards to protect public health.

The criteria pollutants analyzed within this section are nitrogen dioxide (NO₂), sulfur dioxide (SO₂), carbon monoxide (CO), ozone (O₃), and particulate matter (PM). Lead is not analyzed as a criteria pollutant, but lead and other toxic air pollutant emissions impacts are analyzed in the Public Health Section of this document. Two subsets of particulate matter are inhalable particulate matter (less than 10 microns in diameter, or PM₁₀) and fine particulate matter (less than 2.5 microns in diameter, or PM_{2.5}). Nitrogen oxides (NO_x, consisting primarily of nitric oxide [NO] and NO₂) and volatile organic compound (VOC) emissions readily react in the atmosphere as precursors to ozone and, to a lesser extent, particulate matter. Sulfur oxides (SO_x) readily react in the atmosphere to form particulate matter and are major contributors to acid rain. Global climate change and greenhouse gas (GHG) emissions from the proposed project are discussed in Appendix Air-1 and analyzed in the context of cumulative impacts.

In carrying out this analysis, the California Energy Commission (Energy Commission) staff evaluated the following four major issues:

- whether the proposed project is likely to conform with applicable federal, state, and Mojave Desert Air Quality Management District (MDAQMD or District) air quality laws, ordinances, regulations and standards (Title 20, California Code of Regulations, section 1744 (b));
- whether the proposed project is likely to cause new violations of ambient air quality standards or contribute substantially to existing violations of those standards (Title 20, California Code of Regulations, section 1743);
- whether mitigation measures proposed for the proposed project are adequate to lessen potential impacts under the California Environmental Quality Act (CEQA) to a level of insignificance (Title 20, California Code of Regulations, section 1742 (b)); and
- whether the proposed project would exceed regulatory benchmarks identified by and used by staff to analyze National Environmental Policy Act (NEPA) air quality impacts, before or after implementation of recommended mitigation measures.

LAWS, ORDINANCES, REGULATIONS AND STANDARDS (LORS)

The federal, state, and local laws and policies applicable to the control of criteria pollutant emissions and mitigation of air quality impacts for the RSEP are summarized in **Air Quality Table 1**. Staff's analysis examines the project's compliance with these requirements.

Air Quality Table 1
Laws, Ordinances, Regulations, and Standards

Applicable LORS	Description
Federal	
40 Code of Federal Regulations (CFR) Part 52	Nonattainment New Source Review (NSR) requires a permit and requires Best Available Control Technology (BACT) and Offsets. Permitting and enforcement is delegated to Mojave Desert Air Quality Management District (MDAQMD). Prevention of Significant Deterioration (PSD) requires major sources or major modifications to major sources to obtain permits for attainment pollutants. The RSEP is a new source that does not have a rule listed emission source thus the PSD trigger levels are 250 tons per year for NO _x , VOC, SO _x , PM ₁₀ , PM _{2.5} and CO.
40 CFR Part 60	New Source Performance Standards (NSPS), Subpart IIII Standards of Performance for Stationary Compression Ignition Internal Combustion Engines. Establishes emission standards for compression ignition internal combustion engines, including emergency generator and fire water pump engines.
40 CFR Part 93 General Conformity	Requires determination of conformity with State Implementation Plan for projects requiring federal approvals if project annual emissions are above specified levels.
State	
Health and Safety Code (HSC) Section 40910-40930	Permitting of source needs to be consistent with Air Resource Board (ARB) approved Clean Air Plans.
HSC Section 41700	Restricts emissions that would cause nuisance or injury.
California Code of Regulations (CCR) Section 93115	Airborne Toxics Control Measure for Stationary Compression Ignition Engines. Limits the types of fuels allowed, establishes maximum emission rates, establishes recordkeeping requirements on stationary compression ignition engines, including emergency generator and fire water pump engines.
Local (Mojave Desert Air Quality Management District, MDAQMD)	
Rule 201 and 203 Permits Required	Requires a Permit to Construct before construction of an emission source occurs. Prohibits operation of any equipment that emits or controls air pollutant without first obtaining a Permit to Operate.
Rules 401, 402, and 403 Nuisance, Visible Emissions, Fugitive Dust	Limits the visible, nuisance, and fugitive dust emissions and would be applicable to the construction period of the project.
Rule 404 Particulate Matter - Concentration	Limits the particulate matter concentration from stationary source exhausts.
Rule 405 Solid Particulate Matter Weight	Limits the discharge of solid particulate matter based on weight of material processed.
Rule 406 Specific Contaminants	The rule prohibits sulfur compound emissions in excess of 500 ppmv.
Rule 407 Liquid and Gaseous Air Contaminants	The rule prohibits carbon monoxide emissions in excess of 2,000 ppmv.
Rule 409 Combustion Contaminants	Limits the emissions from fossil fuel combustion.
Rule 431 Sulfur Content of Fuels	Limits the sulfur content of liquid fuels to no more than 0.5% by weight.

Applicable LORS	Description
Rule 900 Standard of Performance for New Stationary Source	Incorporates the Federal NSPS (40 CFR 60) rules by reference.
Rule 1303 New Source Review	Specifies BACT/Offsets technology and requirements for a new emissions unit that has potential to emit any regulated pollutants.
Rule 1306 Electric Energy Generating Facilities	Describes actions to be taken for permitting of power plants that are within the jurisdiction of the Energy Commission.

METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

The analysis of proposed project effects must comply with both CEQA and NEPA requirements given the respective power plant licensing authority of the California Energy Commission, land use jurisdictions of BLM and electrical interconnection authority of Western. Because this document is intended to meet the requirements of both NEPA and CEQA, the methodology used for determining environmental impacts of the proposed project includes a consideration of guidance provided by both laws. A significant impact is defined under CEQA as “a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project” (Cal.Code Regs., tit.14 [hereinafter CEQA Guidelines] Section 15382). Questions used in evaluating significance of air quality impacts are based on Appendix G of the CEQA Guidelines (CCR 2006). The specific approach used by Energy Commission staff in determining CEQA significance is discussed in more detail below.

Similarly, NEPA states that “‘Significantly’ as used in NEPA requires considerations of both context and intensity...” (40 CFR 1508.27). Under NEPA, the agency considers three regulatory benchmarks in determining whether a project action would result in an adverse environmental impact when evaluated against the baseline. NEPA requires that an Environmental Impact Statement (EIS) be prepared when the proposed federal action (project) as a whole has the potential to “significantly affect the quality of the human environment.” The three regulatory benchmarks that are used to assess-impacts under NEPA are discussed in more detail below.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

Energy Commission staff assessed five kinds of primary and secondary² impacts: construction, salt commissioning, operation, closure and decommissioning, and cumulative. Construction impacts result from the onsite and offsite emissions occurring during site preparation and construction of the proposed project. Salt commissioning impacts result from the NOx emissions from the oxidation of the magnesium nitrate impurity in the potassium and sodium nitrate salts. Salt conditioning does not directly involve combustion of fossil fuels. However, fossil fuels are used during this time period to provide on-site power using portable, temporary generators due to the remote location of the facility. Operation impacts result from the emissions of the proposed project during operation, which includes the onsite auxiliary equipment emissions (auxiliary cooling units, emergency engines, etc.), the onsite maintenance vehicle

2 Primary impacts potentially result from facility emissions of NOx, SOx, CO and PM10/2.5. Secondary impacts result from air contaminants that are not directly emitted by the facility but formed through reactions in the atmosphere that result in ozone, and sulfate and nitrate PM10/PM2.5.

emissions, and the offsite employee commute and material delivery trip emissions. Closure and decommissioning impacts occur from the onsite and offsite emissions that would result from dismantling the facility and restoring the site. Cumulative impacts analysis assesses the impacts that result from the proposed project's incremental effect viewed over time, together with other closely related past, present, and reasonably foreseeable future projects whose impacts may compound or increase the incremental effect of the proposed project. (Public Resources Code § 21083; Cal. Code Regs., tit. 14, §§ 15064(h), 15065(c), 15130, and 15355.)

METHOD AND THRESHOLD FOR DETERMINING CEQA SIGNIFICANCE

Energy Commission staff evaluates potential impacts per Appendix G of the CEQA Guidelines (CCR 2006). A CEQA significant adverse impact is determined to occur if potentially significant CEQA impacts cannot be mitigated through the adoption of Conditions of Certification. Specifically, Energy Commission staff uses health-based ambient air quality standards (AAQS) established by the ARB and the U.S.EPA as a basis for determining whether a project's emissions will cause a significant adverse impact under CEQA. The standards are set at levels that include a margin of safety and are designed to adequately protect the health of all members of the public, including those most sensitive to adverse air quality impacts such as the aged, people with existing illnesses, children, and infants. Staff evaluates the potential for significant adverse air quality impacts by assessing whether the project's emissions of criteria pollutants and their precursors (NO_x, VOC, PM₁₀ and SO₂) could create a new AAQS exceedance (emission concentrations above the standard), or substantially contribute to an existing AAQS exceedance.

Staff evaluates both direct and cumulative impacts. Staff will find that a project or activity will create a direct adverse impact when it causes an exceedance of an AAQS. Staff will find that a project's effects are cumulatively considerable when the project emissions in conjunction with ambient background, or in conjunction with reasonably foreseeable future projects, substantially contribute to ongoing exceedances of an AAQS. Factors considered in determining whether contributions to ongoing exceedances are substantial include:

1. the duration of the activity causing adverse air quality impacts;
2. the magnitude of the project emissions, and their contribution to the air basin's emission inventory and future emission budgets established to maintain or attain compliance with AAQS;
3. the location of the project site, i.e., whether it is located in an area with generally good air quality where non-attainment of any ambient air quality standard is primarily or solely due to pollutant transport from other air basins;
4. the meteorological conditions and timing of the project impacts, i.e., do the project's maximum modeled pollutant impacts occur when ambient background concentrations are high (such as high wind-blown fugitive dust levels occurring during high wind periods, or seasonally);

5. the modeling methods, and how refined or conservative the impact analysis modeling methods and assumptions were and how that may affect the determined adverse impacts;
6. the project site location and nearest receptor locations; and whether the identified adverse impacts would also occur at the maximum impacted receptor location; and,
7. potential for future cumulative impacts; and whether appropriate mitigation is being recommended to address the potential for impacts associated with likely future projects.

NEPA AIR QUALITY ANALYSIS METHODOLOGY

The National Environmental Protection Act (NEPA) air quality analysis³ considers the following three regulatory benchmarks:

1. The project would exceed General Conformity applicability thresholds for federal nonattainment pollutants. This regulatory threshold applies to both project construction and operation emissions.
2. The project would exceed PSD permit applicability thresholds for federal attainment pollutants. This regulatory threshold only applies to project operation.
3. The project would cause, for federal attainment pollutants, air quality impacts in exceedance of the NAAQS.

If the proposed project were to exceed either of the first two of these regulatory benchmarks then the impacts would be considered potentially adverse and would require a further refined impact and mitigation analysis in order to demonstrate that the proposed project would not result in an adverse impact based on the potential to cause exceedances of the NAAQS. A refined impact and mitigation analysis has been conducted per CEQA requirements, and that analysis is described in detail in this document.

IMPACTS FROM CLOSURE AND DECOMMISSIONING

Impacts from closure and decommissioning, as a one-time limited duration event, are evaluated with the same methods as construction emissions as discussed above.

PROPOSED PROJECT

SETTING AND EXISTING CONDITIONS

Climate and Meteorology

The proposed project is located in California's Sonoran Desert adjacent to the southern border of the Mojave Desert; with the nearest Class I area being Joshua Tree National Park which is approximately 25 miles west of the project site. The project site is approximately 850 feet above mean sea level. The RSEP is in the Mojave Desert Air Basin, which is classified as a dry-hot desert climate. This area is characterized by hot,

³ This is CEC staff's analysis approach that goes beyond the minimum procedural requirements of NEPA.

dry summers and mild winters, with annual rainfall averaging three to seven inches per year. Relatively high daytime temperatures, large variations in relative humidity, large and rapid diurnal temperature changes, occasional high winds, and sand, dust, and thunderstorms characterize the climate of the northeastern Sonoran Desert area. The aridity of the region is influenced by a Pacific sub-tropical high-pressure system typically off the coast of California and topographical barriers that effectively block the flow of moisture to the region. The Mojave Desert Air Basin experiences prevailing winds out of the west and southwest, resulting in a general west-to-east flow across the MDAB.

The highest monthly average high temperature in Vidal is 108°F in July and the lowest average monthly low temperature is 41°F in January and December (WC 2010). Total rainfall in Vidal averages just more than five inches per year with about 50% of the total rainfall occurring during the December through March winter rainy season, and about 30% occurring during the July to September summer monsoon season. Staff reviewed wind data available from the Rice Valley meteorological monitoring station (WRCC 2010), which is located approximately six miles east of the project site. Prevalent winds are out of the west northwest to south during daytime hours and the wind speeds drop and the prevalent direction turns around to be from the north northeast to northeast during nighttime hours.

The applicant also provided a wind rose from the Blythe Airport for the year 2008. This wind data, which is from the same source as the meteorological data used by the applicant in their air dispersion modeling impact analysis, indicates the highest wind direction frequencies for the annual, winter, spring, and fall periods are from the north and the south. Prevailing winds in the MDAB are out of the west and southwest. These prevailing winds are due to the proximity of the MDAB to coastal and central regions and the blocking nature of the Sierra Nevada Mountains to the north; air masses pushed onshore in southern California by differential heating are channeled through the MDAB. The MDAB is separated from the southern California coastal and central California valley regions by mountains (highest elevation approximately 10,000 feet), whose passes form the main channels for these air masses (MDAQMD 2009).

The most recent meteorological (weather) data, collected from the Blythe Airport Meteorological Site located approximately 40 miles southeast of the project site, was for 2008. The measured wind data are graphically represented by Blythe Airport wind roses, provided in the AFC Figure 5.1-C-1b (SR 2009a). These wind roses show that for most of the year, the winds are from the south and the north. Mixing heights in the area, which represent the altitudes where different air masses mix together, are estimated to be on average 230 feet (70 meters) in the morning to as high as 5,250 feet (1,600 meters) above ground level in the afternoon.

Sensitive Receptors

The general population includes many sensitive subgroups that may be at greater risk from exposure to emitted pollutants. These sensitive subgroups include the very young, the elderly, and those with existing illnesses. In addition, the location of the population in the area surrounding a project site may have a large bearing on health risk. The nearest residences are at Vidal Junction, approximately 15 miles northeast. A small cluster of residences is located at the Iron Mountain Pumping Plant, 17 miles west. The nearest

town with significant services is Parker, Arizona, approximately 32 miles east. Blythe, California, is approximately 40 miles south. Twentynine Palms, California, is approximately 75 miles west. There are no sensitive receptors identified within a six-mile radius of the project site.

Existing Ambient Air Quality

The Federal Clean Air Act and the California Clean Air Act both require the establishment of standards for ambient concentrations of air pollutants, called ambient air quality standards (AAQS). The state AAQS, established by the California Air Resources Board, are typically lower (more protective) than the federal AAQS, which are established by the United States Environmental Protection Agency (U.S.EPA). The state and federal air quality standards are listed in **Air Quality Table 2**. The averaging times for the various air quality standards, the times over which they are measured, range from one-hour to an annual average. The standards are read as a concentration, in parts per million (ppm), or as a weighted mass of material per a volume of air, in milligrams or micrograms of pollutant in a cubic meter of air (mg/m^3 or $\mu\text{g}/\text{m}^3$, respectively).

Air Quality Table 2
Federal and State Ambient Air Quality Standards

Pollutant	Averaging Time	Federal Standard	California Standard
Ozone (O ₃)	8 Hour	0.075 ppm ^a (147 µg/m ³)	0.070 ppm (137 µg/m ³)
	1 Hour	—	0.09 ppm (180 µg/m ³)
Carbon Monoxide (CO)	8 Hour	9 ppm (10 mg/m ³)	9.0 ppm (10 mg/m ³)
	1 Hour	35 ppm (40 mg/m ³)	20 ppm (23 mg/m ³)
Nitrogen Dioxide (NO ₂)	Annual	0.053 ppm (100 µg/m ³)	0.03 ppm (57 µg/m ³)
	1 Hour	0.100 ppm (188 µg/m ³) ^b	0.18 ppm (339 µg/m ³)
Sulfur Dioxide (SO ₂)	Annual	0.030 ppm (80 µg/m ³)	—
	24 Hour	0.14 ppm (365 µg/m ³)	0.04 ppm (105 µg/m ³)
	3 Hour	0.5 ppm (1300 µg/m ³)	—
	1 Hour	—	0.25 ppm (655 µg/m ³)
Particulate Matter (PM ₁₀)	Annual	—	20 µg/m ³
	24 Hour	150 µg/m ³	50 µg/m ³
Fine Particulate Matter (PM _{2.5})	Annual	15 µg/m ³	12 µg/m ³
	24 Hour	35 µg/m ³	—
Sulfates (SO ₄)	24 Hour	—	25 µg/m ³
Lead	30 Day Average	—	1.5 µg/m ³
	Calendar Quarter	1.5 µg/m ³	—
Hydrogen Sulfide (H ₂ S)	1 Hour	—	0.03 ppm (42 µg/m ³)
Vinyl Chloride (chloroethene)	24 Hour	—	0.01 ppm (26 µg/m ³)
Visibility Reducing Particulates	8 Hour	—	In sufficient amount to produce an extinction coefficient of 0.23 per kilometer due to particles when the relative humidity is less than 70%.

Source: ARB 2010a.

Notes:

^a The 2008 standard is shown above, but as of September 16, 2009 this standard is being reconsidered. The 1997 8-hour standard is 0.08 ppm.

^b The U.S. EPA is in the process of implementing this new standard, which became effective April 12, 2010. This standard is based on the 3-year average of the 98th percentile of the yearly distribution of the daily 1-hour maximum concentrations.

In general, an area is designated as attainment if the ambient concentration of a particular air contaminant does not exceed the standard. Likewise, an area is designated as non-attainment for an air contaminant if that contaminant standard is violated. In circumstances where there is not enough ambient data available to support designation as either attainment or non-attainment, the area can be designated as unclassified. The unclassified area is normally treated the same as an attainment area for regulatory purposes. An area could be attainment for one air contaminant while non-attainment for another, or attainment for the federal standard and non-attainment for the state standard for the same air contaminant.

The project site is located in the Mojave Desert Air Basin (MDAB) and is under the jurisdiction of the Mojave Desert Air Quality Management District (MDAQMD). The Riverside County portion of the MDAB is designated as non-attainment for the state ozone and PM10 standards. The project site is designated as attainment or unclassified for all federal criteria pollutant ambient air quality standards and the state CO, NO₂, SO₂, and PM2.5 standards. **Air Quality Table 3** summarizes the project site's attainment status for various applicable state and federal standards.

Air Quality Table 3
Federal and State Attainment Status
Project Site Area within Riverside County

Pollutant	Attainment Status ^a	
	Federal	State
Ozone	Unclassified/Attainment ^b	Moderate Nonattainment
CO	Unclassified/Attainment	Unclassified ^b
NO ₂	Attainment ^c	Attainment
SO ₂	Attainment	Attainment
PM10	Unclassified ^b	Nonattainment
PM2.5	Unclassified/Attainment	Unclassified

Source: ARB 2010c, U.S.EPA 2010a.

^a Unclassified is treated the same as Attainment for regulatory purposes.

^b Unclassified/Attainment status for the project site, not the entire MDAB.

^c Attainment status for the new federal 1-hour NO₂ standard is scheduled to be determined by January 2012.

Ambient air quality monitoring data for ozone, PM10, PM2.5, CO, NO₂, and SO₂, compared to most restrictive applicable standards for the years between 2005 through 2009 at the most representative monitoring stations for each pollutant are shown in **Air Quality Table 4**. The 2009 data are preliminary and are not available for all pollutants. Ozone data are from the Blythe-445 West Murphy Street monitoring station. PM10, PM2.5, and CO data are from the Palm Springs-Fire Station monitoring station. The NO₂ data are from the Alamo Lake State Park monitoring station in Arizona. SO₂ data are from the Victorville-14306 Park Avenue monitoring station. **Air Quality Figures 1** and **2** show trends for the 1-hour and 8-hour ozone data for the years 1999 through 2009, and 24-hour PM10 and PM2.5 data for the years 1999 through 2008, respectively.

Ozone

Ozone is not directly emitted from stationary or mobile sources, but is formed as the result of chemical reactions in the atmosphere between directly emitted nitrogen oxides (NO_x) and hydrocarbons (Volatile Organic Compounds [VOCs]) in the presence of sunlight to form ozone. Pollutant transport from the South Coast Air Basin (Los Angeles Area) is one source of the pollution experienced in the eastern Riverside County portion of the MDAB (SCAQMD 2007, p. 1-2).

As **Air Quality Figure 1** indicates, the maximum 1-hour ozone concentrations measured at the eastern border of Riverside County decreased from 1998 to 2003. From 2003 to 2009, the 1-hour and 8-hour maximum ozone concentrations have been relatively stable. The collected air quality data (not shown) indicate that the ozone

violations occurred primarily during the sunny and hot periods typical during May through September.

Air Quality Table 4
Criteria Pollutant Summary
Maximum Ambient Concentrations (ppm or $\mu\text{g}/\text{m}^3$)

Pollutant	Averaging Period	Units	2005	2006	2007	2008	2009 ^g	Limiting AAQS ^c
Ozone	1 hour	ppm	0.084	0.078	0.092	0.074	0.072	0.09
Ozone	8 hours	ppm	0.072	0.059	0.071	0.071	0.066	0.07
PM10 ^{a,b}	24 hours	$\mu\text{g}/\text{m}^3$	66	73	83	75	--	50
PM10 ^{a,b}	Annual	$\mu\text{g}/\text{m}^3$	25.9	28	30	27	--	20
PM2.5 ^a	24 hours	$\mu\text{g}/\text{m}^3$	25	15.8	20.5	17.3	--	35
PM2.5 ^a	Annual	$\mu\text{g}/\text{m}^3$	8.4	7.8	8.6	5.2	--	12
CO	1 hour	ppm	2.1	2.3	1.5	1.0	2.3	20
CO	8 hours	ppm	0.80	0.85	0.79	0.54	0.67	9.0
NO ₂ ^{d,e}	1 hour	ppm	0.011	0.013	--	--	--	0.180
NO ₂ ^{e,f}	1 hour 98 th Percentile	ppm	0.011	0.013	--	--	--	0.100
NO ₂ ^e	Annual	ppm	0.0024	0.0026	--	--	--	0.03

Source: ARB 2010a; ARB 2010b; U.S.EPA 2009; ADEQ 2006; ADEQ 2007

Notes:

^a Exceptional PM concentration events, such as those caused by wind storms are not shown where excluded by U.S.EPA; however, some exceptions events may still be included in the data presented.

^b The PM10 data source is in the Coachella Valley (Palm Springs – Fire Station monitoring station) which is classified as a serious PM10 nonattainment area.

^c The limiting AAQS is the more stringent of the CAAQS or NAAQS for that pollutant and averaging period.

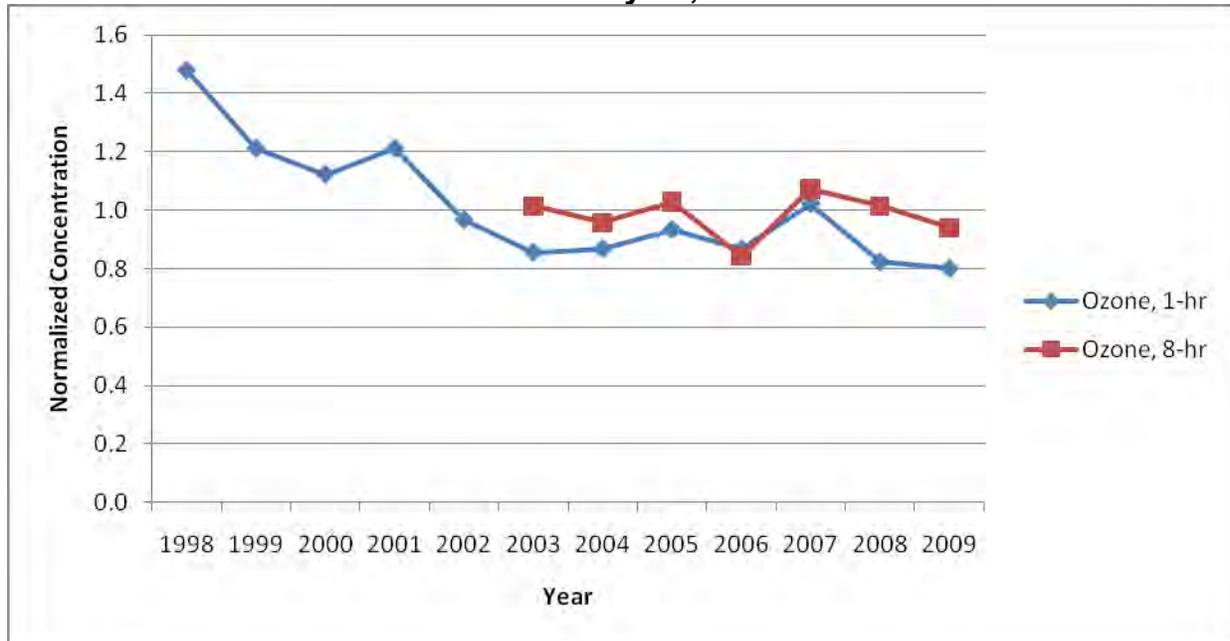

^d The State 1-hour NO₂ standard is based on the annual maximum 1-hour value.

^e The 2005 and 2006 NO₂ data are from the Alamo Lake State Park monitoring station operated by the Arizona Department of Environmental Quality. This station was in operation from May 20 to September 29, 2005, and from April 1 to October 31, 2006.

^f The federal 1-hour NO₂ NAAQS is based on the three-year average of the annual 98th percentile value of daily maximum 1-hour values. Due to the partial coverage for 2006, the annual maximum 1-hour value for the Alamo Lake State Park station is used.

^g Air quality data for 2009 are incomplete and preliminary. The 2009 data were not used to establish background concentrations. Use of the 2006 through 2008 data yield higher background concentrations except for the 1-hour SO₂ value which is suspect.

For Eastern Riverside County
Ozone Data for Blythe, California^{a,b}

Source: ARB 2009; ARB 2010b; U.S.EPA 2009

Notes:

^a The highest measured ambient concentration for a year was divided by the applicable standard to provide a data point for that year. A data point greater than 1.0 means that the measured concentration exceeded the standard. A data point that is less than one means that the respective standard was not exceeded for that year. For example the 8-hour ozone data point in 2008 is 71 ppb/70 ppb standard = 1.01.

^b All ozone data are from Blythe-445 West Murphy Street monitoring station. 8-hr ozone data were not available for this station before 2003.

Particulate Matter (PM10) and Fine Particulate Matter (PM2.5)

PM10 can be emitted directly or it can be formed many miles downwind from emission sources when various precursor pollutants interact in the atmosphere.

The project site is non-attainment for state PM10 standards and unclassified for the federal PM10 standard. **Air Quality Figure 2** shows PM10 and PM2.5 data for the Palm Springs – Fire Station monitoring station. This figure shows large variations from year to year in the maximum measured concentrations and clear exceedances of the state 24-hour PM10 standard. It should be noted that an exceedance does not necessarily mean a violation or nonattainment, as exceptional events do occur and some of those events, which do not count as violations, may be included in the data. The eastern portion of Riverside County where the project site is located is designated as unclassified for the PM10 NAAQS. The San Bernardino County portion of the MDAB which is located immediately north of the project site is designated as nonattainment for the PM10 NAAQS.

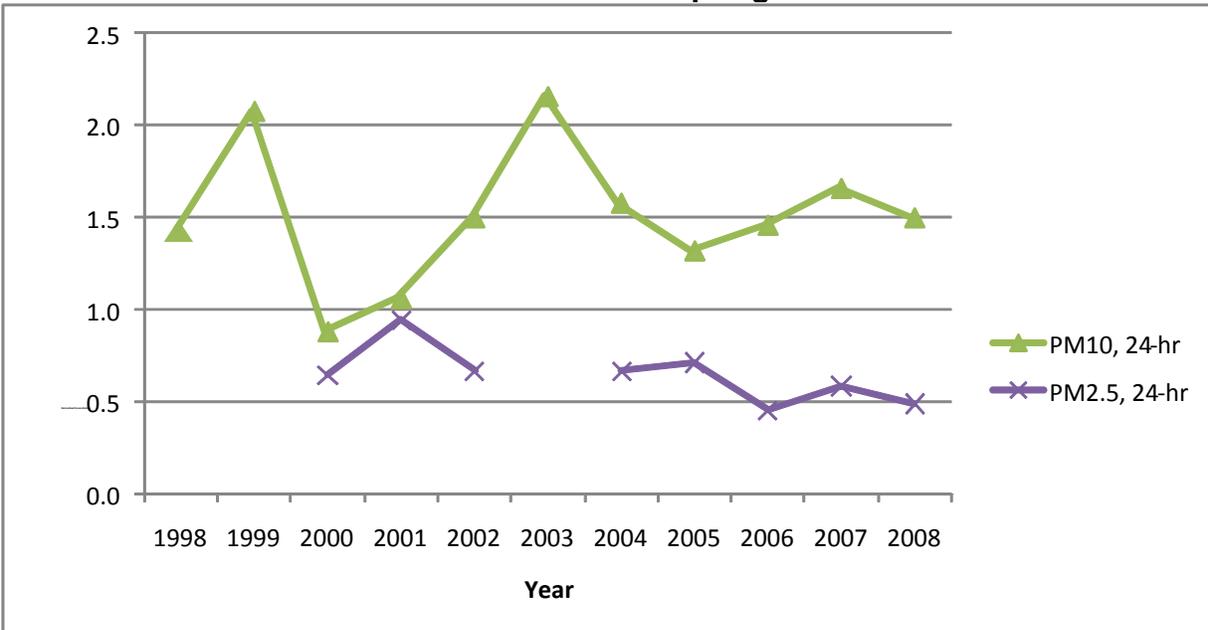

Fine particulate matter, or PM2.5, is produced directly through combustion or indirectly through complex reactions in the atmosphere that involve precursor gases such as SO_x,

NO_x and VOC. PM_{2.5} consists mostly of sulfates, nitrates, ammonium, elemental carbon, and a small portion of organic and inorganic compounds.

The entire MDAB is classified as unclassified/attainment for the federal 24-hour and annual PM_{2.5} standards. The project area is designated unclassified for the state annual PM_{2.5} standard. The differences in the PM₁₀ and PM_{2.5} concentrations indicate that a substantial fraction of the ambient PM₁₀ levels is most likely due to localized fugitive dust sources, such as wind-blown dust, vehicle travel on unpaved roads, or agricultural operations.

Fugitive dust, unlike combustion source particulate and secondary particulate, is composed of a much higher fraction of larger particles than smaller particles, so the PM_{2.5} fraction of fugitive dust is much smaller than the PM₁₀ fraction. Therefore, when PM₁₀ ambient concentrations are significantly higher than PM_{2.5} ambient concentrations, this tends to indicate that a large proportion of the PM₁₀ concentrations are from fugitive dust emission sources, rather than from combustion particulate or secondary particulate emission sources.

1998-2008 Historical Air Quality Data
For Riverside County
PM 10 and PM2.5 Data for Palm Springs – Fire Station^{a,b}

Source: ARB 2009, U.S.EPA 2009

Notes:

^a The highest measured ambient concentration for a year was divided by the applicable standard and to determine the data point for the year. A data point on the chart that is greater than 1.0 means that the measured concentration exceeded the standard, and a point that is less than one means that the respective standard was not exceeded for that year. For example the 24-hour PM10 data point in 2008 is 1,5 which means the measured concentration was 1.5 times the 50 µg/m³ standard or 75 µg/m³.

^b All PM data are from Palm Springs – Fire Station monitoring station. 24-hr PM2.5 data were not available for this station before 2000.

Nitrogen Dioxide

The entire air basin is classified as attainment for the state 1-hour and annual NO₂ standards and the federal annual NO₂ standard. The new federal short-term NO₂ NAAQS was effective as of April 12, 2010 and is based on the three-year average of the annual 98th percentile of the daily maximum 1-hour concentrations. The NO₂ attainment status could change due to the new federal short-term NO₂ standard although a review of the air basin wide monitoring data suggest this would not occur for the MDAB (ARB 2010d). The attainment status review is scheduled to be completed by July 2012.

Approximately 90% of the NO_x emitted from combustion sources is nitric oxide (NO), while the balance is NO₂. NO is oxidized in the atmosphere to NO₂, but some level of photochemical activity is needed for this conversion. The highest concentrations of NO₂ typically occur during the fall. The winter atmospheric conditions can trap emissions near the ground level, but lacking substantial photochemical activity (sun light), NO₂ levels are relatively low. In the summer the conversion rates of NO to NO₂ are high, but the relatively high temperatures and windy conditions disperse pollutants, preventing the accumulation of NO₂.

Carbon Monoxide

The area is classified as unclassified or attainment for the state and federal 1-hour and 8-hour CO standards. The highest concentrations of CO occur when low wind speeds and a stable atmosphere trap the pollution emitted at or near ground level. These conditions occur frequently in the wintertime late in the afternoon, persist during the night and may extend one or two hours after sunrise. The project area has a lack of significant mobile source emissions and has CO concentrations that are well below the state and federal ambient air quality standards.

Sulfur Dioxide

The entire air basin is classified as attainment for the state and federal SO₂ standards. Sulfur dioxide is typically emitted as a result of the combustion of a fuel containing sulfur. Sources of SO₂ emissions within the MDAB come from a wide variety of fuels: gaseous, liquid and solid; however, the total SO₂ emissions within the eastern MDAB are limited due to the limited number of major stationary sources and California's and U.S. EPA's substantial reduction in motor vehicle fuel sulfur content. The project area's SO₂ concentrations are well below the state and federal ambient air quality standards.

Summary

In summary, staff recommends the background ambient air concentrations in **Air Quality Table 5** for use in the modeling and impacts analysis. The recommended background concentrations are based on the maximum criteria pollutant concentrations measured at the most representative monitoring stations closest to the project site.

Where possible, staff prefers that the recommended background concentration measurements come from nearby monitoring stations located in areas with characteristics similar to the project site and that the data cover three years. However, the air quality monitoring network in the MDAB is very sparse. There are relatively few air quality monitoring stations in the MDAB and there are no monitoring stations in proximity to the project site. For this proposed project, the Blythe monitoring station (ozone only), at approximately 40 miles southeast of the project site, is the closest monitoring station. The Alamo Lake State Park monitoring station (NO₂) is located approximately 74 miles to the east in Arizona. The Palm Springs - Fire Station monitoring station (PM₁₀, PM_{2.5}, and CO) is located approximately 100 miles west of the project site. The Victorville monitoring station (SO₂) is located approximately 150 miles west northwest of the project site. In general, the Palm Springs and Victorville monitoring stations are considered to provide very conservative estimates of the worst case background concentrations due to their proximity to the South Coast Air Basin (Metropolitan Los Angeles). As noted earlier, the 2009 air quality data are preliminary and were not used in the determination of background concentrations for the project. If the 2009 data were used, only the 1-hour SO₂ background value would be changed. However, the 2009 maximum 1-hour SO₂ value for Victorville is suspect since it is more than three times the 2009 maximum 3-hour SO₂ value reported for Victorville.

Sources: ARB 2010a; ARB 2010b; U.S.EPA 2010a; U.S.EPA 2010b; ADEQ 2006; ADEQ 2007

a) State 1-hour NO₂ AAQS based on maximum measured 1-hour value

b) National 1-hour NO₂ AAQS based on 3-year average of annual 98th percentile of the daily maximum 1-hour values

Due to the partial coverage of the NO₂ data from the Alamo Lake State Park monitoring station, the applicant was requested to provide additional information supporting the use of these data to represent the background NO₂ concentrations for the project site. In the supplemental information (CH2MHill 2010I), the applicant analyzed several factors relevant to the representativeness of the Alamo Lake data for the project site. These factors included relative proximity of the monitoring stations to the project site, similarity of surrounding land uses, likely stationary and mobile sources of NO_x emissions in proximity to the project site compared to the monitoring stations, seasonal climatology, geography (i.e., terrain) and data quality (i.e., compliance with applicable quality assurance protocols). To address the partial year coverage of the Alamo data, the applicant applied seasonal adjustment factors to increase the measured 1-hour values from the Alamo Lake monitoring station. This adjustment resulted in a 1-hour background NO₂ value to be used in the air quality impact assessment that is approximately 22% higher than the maximum measured 1-hour value. Based on this additional analysis, staff concurs with the applicant's proposed use of the Alamo Lake NO₂ data as the most representative NO₂ data available for the project site.

Monitoring stations located in Imperial County were not considered representative for the project site due to the predominant air flow patterns and due to air pollution from Mexico that creates a significant local influence for the worst-case pollutant concentration readings within Imperial County.

The recommended background concentrations for PM₁₀ in **Air Quality Table 5** are above the most restrictive existing ambient air quality standards, while the recommended background concentrations for the other pollutants are all below the most restrictive existing ambient air quality standards.

The pollutant modeling analysis was limited to the pollutants listed above in **Air Quality Table 5**; therefore, recommended background concentrations were not determined for the other criteria pollutants (ozone, lead, visibility, etc.).

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

Staff provided a number of data requests regarding the construction and operations emissions estimates and air dispersion modeling analysis (CEC 2010b), which the applicant responded to by providing revised emissions estimates and substantially revised and more robust dispersion modeling analysis (CH2MHill 2010a; CH2MHill 2010l; CH2M-Hill 2010m). Staff has reviewed the revised emission estimates and air dispersion modeling analysis and finds them to be reasonable considering the level of emissions mitigation now stipulated to by the applicant.

Project Description

The RSEP is a 150MW concentrating solar thermal power plant with a central receiver tower, sun-tracking heliostat field and an integral thermal storage system using liquid salt as the heat transfer and storage medium. Hot liquid salt is routed to a steam generation system which generates steam for use in a high efficiency reheat steam turbine.

The RSEP site is a privately owned parcel of land located in eastern Riverside County. The site is adjacent to State Route (SR) 62, which parallels a portion of the Arizona-California Railroad and the Colorado River Aqueduct, near the junction of SR 62 and Blythe-Midland Road, and near the sparse remains of the abandoned town of Rice, California. The nearest occupied residences are approximately 15 miles northeast at the rural crossroads community of Vidal Junction, California. A small residential settlement is located at the Metropolitan Water District of Southern California's Iron Mountain Pumping Plant, approximately 17 miles west. The nearest town is Parker, Arizona located approximately 32 miles east of the RSEP site. The town of Blythe, California is located approximately 40 mile to the southeast.

The RSEP would use an air cooled condenser (ACC) to remove waste heat for the steam cycle. Total maximum water consumption would be approximately 180 acre feet per year and would be supplied from on-site wells. Major water uses would be for boiler water makeup and for washing of the heliostats. Smaller volumes of water would be used for an auxiliary cooling system, general plant service water and sanitary uses.

The RSEP steam turbine generator would tie into an on-site, 161/230kV-capable switchyard. From the switchyard, a 10.0 mile, 161/230kV-capable generation tie-line would connect the RSEP to the Western Area Power Administration's existing Parker-Blythe transmission line. The generation tie-line would be constructed partly on federal land and partly on private lands, and would require construction of 4.6 miles of new unpaved access roads and the use of 5.4 miles of existing dirt roads.

No fossil fuels would be used in normal operation of the solar thermal power plant. The RSEP would have no connection to the natural gas pipeline network. Fossil fuel use for normal facility operation would be limited to emergency equipment and plant vehicles, primarily heliostat washing trucks. Fossil fuel (propane or natural gas) would be trucked to the site for use in the salt system commissioning process which would be completed prior to plant commissioning.

Project Emissions

Project Construction

The total duration of project construction for RSEP is estimated to be approximately 27 months. Construction of the RSEP would include the solar receiving tower, the steam turbine power block, up to 17,500 heliostats, molten salt storage tanks, various auxiliary equipment and ancillary structures, and the 10.0-mile long generation tie line. Approximately 1500 acres of the total land holding of 3,324 acres would experience temporary disturbance during construction, resulting in 1,410 acres of permanently disturbed land area which will be enclosed within a security fence.

Onsite and offsite project emissions during construction were divided into three categories: vehicle and construction equipment exhaust, fugitive dust generated by vehicles and construction equipment, and windblown fugitive dust. Construction equipment exhaust emissions were estimated using URBEMIS2007 emission factors. Fugitive dust emissions were estimated using EPA-approved emission factors and methodology published in AP-42 (U.S.EPA 2006a, U.S.EPA 2006b). The EPA-approved emission factors were reduced by 68% based on the South Coast Air Quality Management District (SCAQMD) CEQA handbook (SCAQMD 1993). Per the SCAQMD handbook, the reduction would be achieved by watering traveled roads twice a day. Fugitive dust emissions from soil disturbance (e.g., grading activities) were estimated based on the controlled emission factor published in URBEMIS. The controlled emission factor assumed 50% control of fugitive dust emissions by applying water to the disturbed surface. Fugitive dust emissions from wind-erosion of material stockpiles were estimated using the SCAQMD CEQA handbook. On-road exhaust emissions were estimated using EMFAC2007 (version 2.3) emission factors. On-road and off-road exhaust emissions also were calculated assuming construction fleets would use ultra low sulfur diesel (ULSD) fuel, the only diesel fuel approved for sale in California. Due to the remote location of the project site, the applicant proposed to use small diesel engine-powered electrical generators and water pump during construction. These diesel engines would be temporary sources permitted by the MDAQMD and would be required to meet the applicable NSPS and ARB emission limits.

Offsite construction emissions would also occur during the 6 months of construction for the 10.0-mile-long generator tie-line. Offsite emission sources include the exhaust emissions from construction equipment, motor vehicles traveling to and from the planned work sites and fugitive dust from construction activities and vehicle travel on roadways. The emission calculation methodology for the offsite construction activities was similar to the methodology for estimating onsite construction emissions.

The maximum daily emissions were estimated based on the month with the projected maximum operations of construction equipment, heavy-duty truck operations, fugitive dust, and projected roundtrip workforce commuting trips, divided by the number of days of operation within that month. Maximum annual emissions were estimated based on the number and type of construction equipment, the number of heavy-duty trucks, fugitive dust, and the roundtrip workforce commutes projected for each month of construction. The maximum annual construction emissions were estimated as the sum of the maximum monthly emissions over a 12-month period.

The maximum daily and annual construction emissions are presented in **Air Quality Tables 6 and 7**.

Commissioning of Salt System

The commissioning process for the salt system would involve the melting, heating, and conditioning of approximately 70 million pounds (35,000 tons) of sodium nitrate and potassium nitrate salts. The salt commissioning process would take approximately 140 days and would begin in Month 18 of the construction schedule. The other construction activities and their associated emissions would continue during the salt system commissioning activities.

The salt melting and heating phases of the commissioning process would produce emissions of criteria pollutants from the combustion of gaseous fuels in two temporary, gas-fired convection heaters with rated capacities of 55 million British thermal units per hour (MMBtu/hr) and 20 MMBtu/hr. Propane and natural gas (compressed or liquefied) are the candidate gaseous fuels. The highest emission rates among the candidate fuels were used to estimate emissions. The estimates for NOx emissions from the two heaters assume use of ultra-low NOx burners and flue gas recirculation. Fugitive emissions from the handling, milling and conveying of the solid salts would be collected and exhausted through a fabric filter baghouse unit and salt handling and milling

equipment would be located in an enclosure. The salt melting and heating operations would run 24 hours per day and 7 days a week until the 35,000 tons of salt have been processed.

The salt conditioning phase of the salt commissioning process would result in NO_x emissions (as NO₂) from the oxidation of magnesium nitrate that is present as a trace impurity in the potassium nitrate and sodium nitrate salts. The salt conditioning phase does not directly involve combustion of fossil fuels. The NO_x emissions estimate for the salt conditioning phase assumes that the amount of magnesium nitrate impurity in the potassium and sodium nitrate salts would be at the maximum amount allowed in the vendor guarantee and that all of the magnesium nitrate would be oxidized and released as NO₂ during the conditioning phase. To reduce NO_x emissions from the oxidation of the magnesium nitrate impurity, the vent streams from the salt heater and the hot storage tank would be routed through a multi-stage chemical wet scrubber with an assumed control efficiency of 85%. The analysis assumes a constant NO_x emission rate from the magnesium nitrate oxidation but the actual NO_x emission rate is expected to be lower since the average magnesium nitrate content is likely to be lower than the vendor guarantee and the overlap of the melting, heating and conditioning phases of the commissioning process.

After salt system commissioning is completed, the salt handling system, the baghouse, the two fossil fuel-fired heaters and the NO_x scrubber system would be dismantled and removed from the project site. Barring a catastrophic event, the applicant has stated that there would be no need to add additional salt to the molten salt system after the initial commissioning of the system. The design for the molten salt system provides a “volume margin” of 2% to cover nominal leaks and releases over the 30-year life of the molten salt system. Consequently, there would be no future salt treatment required and no future emissions from fossil-fueled heaters.

The criteria pollutant emissions estimated for the salt commissioning process are presented in **Air Quality Table 8**. The emissions from the melting and heating phases are from the combustion of the gaseous fuel in the heaters. The emissions from the conditioning phase are from the oxidation of the magnesium nitrate trace contaminant. The estimated durations of the melting, heating and conditioning phases are 91, 36 and 69 days, respectively.

Salt Trace Contaminants

The dry potassium nitrate and sodium nitrate salts contain trace contaminants including several metals and metal salts, most notably magnesium nitrate. The applicant proposes to limit the trace contaminants by using maximum allowable (i.e., “not to exceed”) specifications for the specific, detectable contaminants when procuring the salts. The applicant states that the only metal contaminants present at levels above the detection allowance (i.e., detection threshold) are magnesium and iron. Both of these metals would be oxidized during the salt conditioning phase to form magnesium oxide and iron oxide. Both of these oxides would be non-volatile and would remain in solid form in the molten salt system throughout the life of the system. For those metals below the detection threshold, the applicant states that the metals are also non-volatile and would remain in the salt system. (CH2MHill 2010a; CH2Mhill 2010m)

During the salt conditioning process, the magnesium nitrate is oxidized to form magnesium oxide, nitrogen dioxide (NO₂) and oxygen. The emissions of NO₂ would be controlled with a multi-stage wet scrubber during the salt conditioning.

Overlap of Construction and Salt Commissioning

To assess the impacts during the salt commissioning period, the applicant assumed that the individual melting, heating, and conditioning steps in the overall salt system commissioning process would occur concurrently. In addition, since the salt commissioning would be done during months 18 to 21 of construction, the applicant modeled the maximum construction emissions that would occur concurrently with the salt commissioning emissions.

Initial Project Commissioning

The initial project commissioning would occur during the final months of construction and would follow the salt system commissioning activities. Project commissioning would include the power block commissioning work such as steam blows and steam turbine startup activities. The power block commissioning activities would not result in the combustion of fossil fuels, nor would the wet surface air cooler (WSAC) unit be in

operation. As a result, no additional emissions of air pollutants would occur during the power block commissioning phase.

Project Operation

The RSEP facility would be a nominal 150 MW concentrating solar thermal electrical generating facility. The direct air pollutant emissions from power generation would be negligible; however, there would be emissions from auxiliary equipment, routine testing of emergency equipment and various maintenance activities necessary to operate and maintain the facility.

The following are the stationary and mobile emission source operating assumptions that were used to develop the operation emissions estimates for RSEP:

Stationary emission sources

- Emergency fire water pump engines (2 total): 600 hp diesel-fired engines. Operation for testing and maintenance not to exceed 30 minutes per test, and not to exceed 26 hours per year. The applicant must conduct weekly, 30-minute test runs of the diesel engine fire pumps to comply with the requirements of the National Fire Protection Association for this equipment (NFPA 25, Chapter 5)
- Emergency generator engines (2 total): 4,020 hp diesel-fired engines. Operation for testing and maintenance not to exceed 60 minutes per test, and not to exceed 26 hours per year. The applicant must conduct regular testing and maintenance of the emergency generators to comply with the manufacturer's maintenance guidelines. Due to several factors including the larger size of the diesel engines used for the emergency generators, a longer test run (60 minutes vs. 30 minutes) is recommended by the manufacturer.
- Wet surface air cooling system (Two two-cell units): Total recirculation rate of 2,736 gallons per minute. Used to remove residual heat from balance of plant (BOP) equipment. The WSAC system would have a maximum run time of 4,400 hours per year and a maximum drift rate of 0.0005%.

Mobile emissions sources

Mobile emissions sources required for operation and maintenance were estimated by the applicant based on vehicle miles traveled (VMT) and operating hours. Each mobile source category has a different basis for emissions estimates as provided in the applicant's estimate spreadsheets (SR 2009a: Appendix 5.1B and CH2MHill 2010a)

The daily and annual emissions for the RSEP onsite stationary and onsite and offsite mobile sources for the Operations phase are summarized in **Air Quality Tables 9 and 10**.

Salt losses during operations

The molten salt system includes two large molten salt storage tanks. Normal operations involve the transfer of molten salt from the "cold" storage tank (nominal temperature 550°F) through the solar receiver to the "hot" storage tank (nominal temperature 1050°F). The hot salt would be routed through a heat exchanger to generate steam and then

back to the cold storage tank. For normal operations of the RSEP, this transfer of molten salt would occur on a daily basis. As the volume of the molten salt in a storage tank increases, the space above the molten salt is exhausted through vents to the atmosphere. As the volume of molten salt in a storage tank decreases, ambient air is drawn into the tank through vents. The applicant analyzed the potential for emissions to the atmosphere from this “cycling” of the ullage space above the molten salt in the storage tanks and has stated that there would be no salt loss and no “fumes” from these normal venting operations.

As noted above, barring a catastrophic event, the applicant has stated that there would be no need to add additional salt to the molten salt system after the initial commissioning of the system. The design for the molten salt system provides a “volume margin” of 2% to cover nominal leaks and releases over the 30-year life of the molten salt system.

Dispersion Modeling Assessment

The emissions from a proposed project are the actual mass of pollutants that would be emitted from the project to the atmosphere. The impacts for a proposed project are the concentration of pollutants that would occur at ground level due to the emissions from the project. When pollutants are emitted at a high temperature and velocity through a relatively tall stack, the pollutants would be greatly diluted by the time they reach ground level. For the proposed Rice project there are no very tall emission stacks, but the construction and maintenance vehicles and emergency engines do have relatively high-temperature and high-velocity exhausts. The heaters used for the salt system commissioning also have relatively high exhaust temperatures and velocities. The emissions from the proposed project, both stationary source and onsite mobile source emissions, were analyzed through the use of air dispersion models to determine the probable impacts at ground level.

Air dispersion models provide a means of predicting the ground level magnitude of the impacts of the emissions from a proposed project at locations around the project site. These dispersion models consist of a set of complex mathematical equations, which are repeatedly solved by a computer for many ambient conditions to provide an estimate of the maximum offsite pollutant concentrations. The model results are generally described as maximum concentrations, in units of mass per volume of air, such as micrograms per cubic meter ($\mu\text{g}/\text{m}^3$).

The applicant used the U.S.EPA guideline model ISCST3 (version 02035) and the SCREEN3 meteorological set and local terrain to estimate ambient impacts from project construction, salt system commissioning and operation. The SCREEN3 meteorological data set contained a matrix of 54 different combinations of wind speed and stability classes designed to evaluate a full range of possible 1-hour average meteorological conditions. The additional short-term and annual concentrations at each receptor were then calculated based on the 3-hour, 8-hour, 24-hour, and annual persistence factors outlined in EPA's *Screening Procedures for Estimating the Air Quality Impact of Stationary Sources* (EPA, 1992).

The construction emission sources for the site were grouped into three categories: vehicle and construction equipment exhaust, fugitive dust from vehicle and construction equipment, and windblown fugitive dust. Due to the remote location of the project site, the applicant is proposing the use of temporary, diesel engine-powered electrical generators to provide onsite power. The exhaust emissions from these temporary generators were also included in the construction emissions. The exhaust emissions

and the fugitive dust emissions from vehicles and equipment were modeled as volume sources. Wind-blown fugitive dust emissions were modeled as an area source.

To assess the impacts during the salt commissioning period, the applicant assumed that the individual melting, heating, and conditioning processes would occur concurrently. In addition, since the salt commissioning would be done during months 18 to 21 of construction, the applicant modeled the maximum construction emissions along with the salt commissioning emissions. The two heaters used to melt and heat the salt were modeled as point sources. The NO_x emissions from the multi-stage wet chemical scrubber were modeled as a point source. Because the commissioning phase is a one-time activity and is expected to be completed within a 5-month period, annual impacts were not assessed. The emissions from the emergency generators and diesel fire pumps also were not included as part of the RSEP salt commissioning assessment.

The impact assessment for the RSEP operations addressed the four, permanent diesel-fired emergency engines, the wet surface air cooler and the exhaust and fugitive dust emissions from the maintenance vehicles. The four emergency diesel engines (two diesel engine-powered fire water pumps and two diesel engine-powered emergency electrical generators) and the WSAC were modeled as point sources and the exhaust and fugitive dust emissions from the maintenance vehicles were modeled as volume sources.

The inputs for the air dispersion models included stack information (exhaust flow rate, temperature, and stack dimensions), specific engine and vehicle emission data, site elevation data and meteorological data, such as wind speed, wind direction and atmospheric conditions.

The results from the screening modeling showed 1-hour NO₂ impacts below but close to the state 1-hour NO₂ standard. Due to these relatively high 1-hour NO₂ impacts from the screening analysis and to assess compliance with the new federal 1-hour NO₂ ambient air quality standard that became effective on April 12, 2010, the applicant remodeled the construction, salt commissioning, and operation emissions using more sophisticated modeling techniques based on the EPA AERMOD dispersion model (version 09292) and the ozone limiting method (OLM).

NO_x emissions from internal combustion sources, such as diesel engines, are primarily in the form of nitric oxide (NO) rather than NO₂. The NO oxidizes into NO₂ in the atmosphere, primarily through the reaction with ambient ozone. The NO_x OLM calculates ambient NO₂ concentrations based on the assumption that all ambient ozone reacts with the stack NO emissions to form NO₂. The applicant used the default assumption of an initial NO₂/NO_x ratio of 0.1 for all NO_x emission from combustion sources. Hourly ozone monitoring data from Niland, California were used for all of 2002 and January through April of 2003, and from Blythe for May 2003 through 2004, to correspond with the hourly meteorological data from the Blythe Airport. The applicant used these hourly ozone and meteorological data and the maximum hourly NO_x emission rates to estimate maximum hourly NO₂ impacts.

For the 1-hour NO₂ re-modeling, the receptor locations were consistent with the receptor locations used for previous screening modeling analysis. Source locations,

parameters, and emission rates for the construction and salt commissioning remodeling were also consistent with those used in the previous screening modeling. As the project planning progressed, the applicant determined that larger emergency generators were needed so the applicant replaced the two 3,600 hp Caterpillar diesel generators with two 4,020 hp Caterpillar units to provide the higher rated electrical output required for the RSEP emergency electrical power. Based on manufacturer's requirements, the applicant increased the run time for routine testing and maintenance of the emergency generators to 60 minutes per test. The emission rates and exhaust parameters for the operations scenario were updated to reflect the new, larger engines and longer run time for the maintenance testing for the emergency diesels (CH2MHill 2010l).

Staff reviewed the background concentrations provided by the applicant and made some minor adjustments to arrive at the ambient background concentrations shown in **Air Quality Table 5**. As noted above, based on the additional analysis completed by the applicant, staff concurs with the use of the NO₂ data from the Alamo Lake State Park monitoring station. Staff added the modeled impacts to these background concentrations, and then compared the results with the ambient air quality standards for each respective air contaminant to determine whether the proposed project's emission impacts would cause a new exceedance of an ambient air quality standard or would contribute to an existing exceedance.

To assess compliance with the state 1-hour NO₂ standard, the maximum estimated 1-hour impact from the three-year period 2002 through 2004 was added to the background 1-hour NO₂ value from **Air Quality Table 5**. To evaluate compliance with the national 1-hour NO₂ standard, the three year average of the annual eighth highest modeled impact from the three years 2002, 2003 and 2004 was added to the adjusted maximum 1-hour NO₂ value measured at the Alamo Lake State Park site.

The following sections discuss the proposed project's direct air quality impacts from construction, salt commissioning and operation, as estimated by the applicant, and appropriate mitigation.

Construction Impacts and Mitigation

Using estimated peak hourly construction equipment exhaust emissions and fugitive emissions, the applicant modeled the proposed project's maximum 1-hour impacts due to construction emissions. The additional short-term and annual concentrations at each receptor were then calculated based on the 3-hour, 8-hour, 24-hour, and annual persistence factors (U.S.EPA 1992). To determine the construction impacts relative to the ambient air quality standards (i.e., 1-hour through annual), the predicted off-site impacts were added to a conservatively estimated background concentration levels (**Air Quality Table 5**) to determine the total impacts. The results of the applicant's modeling analysis for the construction impacts are presented in **Air Quality Table 11**. The construction modeling analysis includes both the onsite fugitive dust and vehicle tailpipe emission sources estimated by the applicant which are summarized in **Air Quality Tables 6 and 7**, and which include the applicant's proposed control measures. The 1-hour NO₂ impacts were assessed using the more sophisticated remodeling protocol described above.

This modeling analysis indicates, with the exception of PM10 that the proposed project would not create new exceedances or contribute to existing exceedances for any of the modeled air pollutants. The conditions that would create worst-case project modeled PM10 impacts (low wind speeds) are not the same conditions when worst-case background PM10 is expected. Additionally, the worst-case project PM10 impacts occur at the fence line and drop quickly with distance from the fence line. Therefore, staff concludes that the construction impacts, when considering staff's mitigation measures would not contribute significantly to exceedances of PM10 standards.

However, in light of the existing PM10 and ozone non-attainment status for the project site area, staff considers the construction NOx, VOC, and PM emissions to be potentially CEQA significant and recommends that the off-road equipment and fugitive dust emissions be mitigated pursuant to CEQA.

The modeling analysis shows that, after implementation of the recommended emission mitigation measures, the proposed project's construction is not predicted to cause new exceedances of the NAAQS. Therefore, it has been determined that no adverse NEPA impacts would occur after implementation of the recommended mitigation measures.

Construction Mitigation

Applicant's Proposed Mitigation

To mitigate the impacts due to construction of the facility, the applicant proposed several construction mitigation measures (SR 2009a, Section 5.1.6.1)

Adequacy of Proposed Mitigation

Staff generally concurs with the applicant's proposed construction mitigation measures but has determined that additional mitigation is needed to achieve mitigation comparable to other larger solar projects, to maintain impacts below levels of significance, and to conform to LORS.

Staff Proposed Mitigation

Staff recommends the applicant's proposed construction mitigation be formalized, with additions and modifications to meet current staff recommendations, in staff Conditions of Certification **AQ-SC1** through **AQ-SC5**. Staff has determined that the proposed conditions of certification would mitigate the construction air quality impacts for the proposed project air quality impacts to less than significant pursuant to CEQA.

Staff has considered the minority population surrounding the site (see Socioeconomics Figure 1). Since the proposed project's direct air quality impacts have been reduced to less than significant, there is no environmental justice issue for air quality.

Salt Commissioning Impacts and Mitigation

The current project schedule calls for the commissioning of the salt system to be completed during months 18 through 21. The applicant estimated the potential 1-hour air quality impacts resulting from simultaneous construction and salt commissioning activities by modeling the maximum predicted emissions from construction activities during months 18 through 21 with the maximum estimated emissions from the salt commissioning. The additional concentrations at each receptor were then calculated based on the 3-hour, 8-hour, 24-hour and annual persistence factors (U.S.EPA 1992). Estimates of the annual average impacts were developed even though the emissions specific to the salt commissioning activities would occur only once during the project lifetime and would be completed within a 5-month period. To determine the salt commissioning impacts relative to the ambient air quality standards except for the 1-hour NO₂ standards, the predicted project impacts were added to conservatively estimated background concentration levels (**Air Quality Table 5**) to determine the total impacts. The 1-hour NO₂ impacts were assessed using the more sophisticated Ozone Limiting Method (OLM) modeling protocol described above. As summarized in **Air Quality Table 12**, the maximum predicted NO₂, CO, SO₂, and PM_{2.5} concentrations combined with the background concentrations are less than the AAQS. Therefore, NO₂, CO, SO₂, and PM_{2.5} impacts from commissioning would be less than significant.

For PM10, the 24-hour and annual background concentrations exceed the state AAQS without adding the modeled concentrations. As a result, the predicted impacts also would be greater than the AAQS. However, the salt commissioning activity would be of limited duration and the use of clean-burning fuels (natural gas or propane) would meet the best available control technology requirements for particulate emissions from the two heater units.

Therefore, the salt commissioning phase of the proposed project would result in minimal PM10 impacts that are not expected to contribute significantly to existing violations of the PM10 AAQS. With implementation of best available fugitive dust emission control techniques and other proposed mitigation measures as required in staff conditions **AQ-SC1** through **AQ-SC5** to minimize construction impacts, the combined PM10 impacts from the construction and salt commissioning activities are not expected to be significant.

Staff has considered the minority population surrounding the site (see **Socioeconomics Figure 1**). Since the proposed project's direct air quality impacts have been reduced to less than significant, there is no environmental justice issue for air quality.

AIR QUALITY TABLE 12

Operation Impacts and Mitigation

The following section discusses the proposed project's direct operating ambient air quality impacts, as estimated by the applicant, and evaluated by staff. Additionally, this section discusses the recommended mitigation measures.

Operation Modeling Analysis

Using estimated peak hourly operations equipment exhaust emissions and fugitive and exhaust emissions from maintenance vehicles, the applicant modeled the proposed project's maximum 1-hour impacts due to operations emissions. The additional short-term and annual concentrations at each receptor were then calculated based on the 3-hour, 8-hour, 24-hour, and annual persistence factors (U.S.EPA 1992). The 1-hour NO₂ impacts were assessed per the more sophisticated remodeling protocol based on the EPA AERMOD dispersion model (version 09292) and the ozone limiting method (OLM) described above. To determine the operations impacts relative to the ambient air quality standards (i.e., 1-hour through annual), the predicted off-site impacts were added to conservatively estimated background concentration levels (**Air Quality Table 5**) to determine the total impacts. The results of the applicant's modeling analysis for the operations impacts are presented in **Air Quality Table 13**. The operations modeling analysis includes both the onsite fugitive dust and vehicle tailpipe emission sources estimated by the applicant which are summarized in **Air Quality Tables 9 and 10**, and which include the applicant's proposed control measures.

This modeling analysis indicates, with the exception of the 24-hour and annual PM₁₀ impacts that the proposed project would not create new exceedances or contribute to existing exceedances for any of the modeled air pollutants. The conditions that would create worst-case project modeled PM impacts (low wind speeds) are not the same conditions when worst-case background is expected for PM₁₀. Additionally, the worst-case PM₁₀ impacts from the project occur at the fence line and drop quickly with distance from the fence line. Therefore, staff concludes that the operation impacts, when considering the proposed mitigation measures would not contribute substantially to exceedances of the PM₁₀ CAAQS.

AIR QUALITY TABLE 13
Maximum Modeled Impacts for Operations Phase and the Ambient Air Quality Standards

Pollutant	Averaging Period	Maximum Modeled Concentration^a (µg/m³)	Background Concentration^b (µg/m³)	Total Predicted Concentration (µg/m³)	State Standard (µg/m³)	Federal Standard (µg/m³)	Percent of State Standard	Percent of Federal Standard
NO ₂	1-hour State ^c	179	29.4	208.4	339	---	61%	---
	1-hour National ^d	126	29.4	155.4	---	188	---	83%
SO ₂	Annual	0.33	4.9	5.2	57	100	9%	5%
	1-hour	0.60	47	47.6	655	—	7%	---
	3-hour	0.39	31	31.4	—	1,300	---	2%
	24-hour	0.01	13	13.0	105	365	12%	4%
CO	Annual	0.00038	4	4.0	—	80	---	5%
	1-hour	80	2645	2725	23,000	40,000	12%	7%
PM ₁₀	8-hour	13	944	957	10,000	10,000	10%	10%
	24-hour	8.2	83	91.2	50	150	182%	61%
PM _{2.5}	Annual	1.2	30.5	31.7	20	—	159%	---
	24-hour	1.7	20.5	22.2	—	35	---	63%
	Annual	0.1	8.7	8.8	12	15	73%	59%

a) Source: SR 2009a; CH2MHill 2010a;CH2MHill 2010e; CH2M-Hill 2010l

b) Source: Air Quality Table 5

c) State 1-hour NO₂ AAQS based on maximum measured 1-hour value

d) National 1-hour NO₂ AAQS based on 3-year average of annual 98th percentile maximum daily 1-hour values

However, in light of the existing PM10 and ozone non-attainment status for the project site area, staff considers the operation NOx, VOC, and PM emissions to be potentially CEQA significant and recommends that the off-road equipment and fugitive dust emissions be mitigated pursuant to CEQA.

The modeling analysis shows that, after implementation of the recommended emission mitigation measures, the proposed project's operation is not predicted to cause new exceedances of the NAAQS. Therefore, it has been determined that no adverse NEPA impacts would occur after implementation of the recommended mitigation measures.

Operation Mitigation

Applicant's Proposed Mitigation

Emission Controls

As discussed in the air quality section of the AFC and Data Responses (SR 2009a; CH2MHill 2010a; CH2M-Hill 2010m), the applicant proposes the following Best Available Control Technology (BACT) emission controls on the stationary equipment associated with the RSEP:

Emergency Generator Engines

The applicant has proposed two 4,020 brake horsepower (bhp) diesel engine emergency generators, which would be fired on ARB diesel fuel. The applicant has proposed ARB/EPA Tier 2 engines, compliant with the New Source Performance Standards, Subpart IIII Standards of Performance for Stationary Compression Ignition Internal Combustion Engines, for the emergency generators. This is the lowest emitting Tier for this size of emergency generator engine. The proposed ARB/EPA Tier 2 engines would have the following emission guarantees:

- NOx: 5.09 gram/bhp-hour
- NMHC: 0.10 gram/bhp-hour
- CO: 0.63 gram/bhp-hour
- PM10/PM2.5: 0.03 gram/bhp-hour
- SOx: ARB diesel fuel (15 ppm sulfur)

Fire Water Pump Engines

The applicant has proposed two 600 bhp fire water pump engines, which would be fired on ARB diesel fuel. The applicant has proposed ARB/EPA Tier 3 engines, compliant with the New Source Performance Standards, Subpart IIII Standards of Performance for Stationary Compression Ignition Internal Combustion Engines, for the fire water pumps. The proposed ARB/EPA Tier 3 engines would have the following emission guarantees:

- NMHC + NOx: 3.0 gram/bhp-hour
- CO: 2.6 gram/bhp-hour
- PM10/PM2.5: 0.15 gram/bhp-hour

- SO_x: ARB diesel fuel (15 ppm sulfur)

Cooling Towers

The applicant has proposed a wet surface air cooling (WSAC) system comprising two two-cell units which would be used for auxiliary cooling. The WSAC system would have a high efficiency drift eliminator guaranteed to control drift to 0.0005% of the water recirculation rate. Additionally, the cooling tower recirculating water would be controlled to have a maximum total dissolved solids content of 2,000 ppm. The cooling unit would have the following emission limits, each:

- PM₁₀/PM_{2.5}: 0.014 lb/hour, 0.36 lb/day, 0.034 tons/year

Operation and Maintenance Vehicles

Staff recommends additional mitigation measures for operation and maintenance vehicles for the RSEP to be consistent with the mitigation measures for other recent large solar power projects. These measures include the following requirements:

- Only new on-road and off-road vehicles meeting California on-road vehicle and U.S. EPA and California off-road emission standards would be purchased for use at the site.
- Fugitive dust control measures for operation are recommended that include the same mitigation measures as required during construction, as appropriate.

Adequacy of Proposed Mitigation

Staff concurs with the District's preliminary determination that the proposed project's stationary source proposed emission controls/emission levels for criteria pollutants meet regulatory requirements and that the proposed stationary source emission levels are reduced adequately.

Additionally, staff generally agrees that the applicant's proposed fugitive dust mitigation measures and the additional fugitive dust mitigation measures recommended by staff would provide adequate fugitive dust emission control.

Staff Proposed Mitigation

As mentioned earlier in the discussions of the ozone and PM₁₀ impacts, staff concludes that the proposed project's direct stationary source ozone precursor and PM₁₀ emissions are minimal, but when combined with the maintenance vehicles emissions could be significant. Additionally, staff believes that a solar renewable project, which would have a 30-year life in a setting likely to continue to be impacted by both local and upwind emission sources, should address its contribution to the potentially ongoing nonattainment of the PM₁₀ and ozone standards. Staff concludes that the applicant's proposed mitigation measures the staff's recommended mitigation measures are consistent with current mitigation requirements for other large solar projects and would adequately mitigate the proposed project's stationary source, mobile equipment, and fugitive dust emissions. Therefore, staff recommends the operating mitigation be formalized, with minor modifications to meet current staff recommendations, in staff Conditions of Certification **AQ-SC6** and **AQ-SC7**.

Staff is also proposing Condition of Certification **AQ-SC8** to ensure that the Energy Commission license is amended as necessary to incorporate changes to the air quality permits.

Operation of the molten salt system involves routine venting to the atmosphere of the headspace in the molten salt storage tanks. Staff recommends **AQ-SC9** which requires a source test plan to quantify the NO_x and PM emissions from the tank venting and an analysis to confirm that these emissions are negligible.

Staff has determined that the proposed emission controls and emission levels, along with the applicant proposed and staff recommended emission mitigation measures, would mitigate all proposed project air quality impacts to less than significant pursuant to CEQA.

Staff has considered the minority population surrounding the site (see **Socioeconomics Figure 1**). Since the proposed project's direct air quality impacts have been reduced to less than significant, there is no environmental justice issue for air quality.

Indirect Pollutant and Secondary Pollutant Impacts

Project would have direct emissions of chemically reactive pollutants (NO_x, SO_x, and VOC), but would also have indirect emission reductions associated with the reduction of fossil-fuel fired power plant emissions due to the proposed project displacing the need for their operation, since solar renewable energy facilities would operate on a must-take basis⁴. However, the exact nature and location of such reductions is not known. It is reasonable to assume that some of the reductions would occur at power plants within the Mojave Desert Air Basin (MDAB), such as at the Blythe Energy Project facility, but most reductions would occur outside of the MDAB including upwind areas such as the South Coast Air Basin since the electricity supplied by this proposed project would be directed to Southern California Edison (SCE) transmission lines. However, estimates of local emission reductions or the downwind impact of the upwind emission reductions would be speculative, so the discussion below focuses on the direct emissions from the proposed project within the Riverside County portion of the MDAB.

Ozone Impacts

There are air dispersion models that can be used to quantify ozone impacts, but they are used for regional planning efforts where hundreds or even thousands of sources are input into the model to determine ozone impacts. There are no regulatory agency models approved for assessing single source ozone impacts. However, because of the known relationship of NO_x and VOC emissions to ozone formation, it can be said that the emissions of NO_x and VOC from the RSEP would have the potential (if left unmitigated) to contribute to higher ozone levels in the region. These impacts would be cumulatively significant under CEQA because they would contribute to ongoing violations of the state ozone ambient air quality standards.

⁴ This refers to the fact that the contract between the owner of this solar power facility and the utility will require that the utility take all generation from this facility with little or no provisions for the utility to direct turn down of generation from the facility.

PM2.5 Impacts

Secondary particulate formation, which is assumed to be 100% PM2.5, is the process of conversion from gaseous reactants to particulate products. The process of gas-to-particulate conversion, which occurs downwind from the point of emission, is complex and depends on many factors, including local humidity and the presence of air pollutants.

The Riverside County portion of the Mojave Desert Air Basin has not undergone the rigorous secondary particulate studies that have been performed in other areas of California, such as the San Joaquin Valley, that have more serious fine particulate pollution problems. However, because of the known relationship of NOx and SOx emissions to PM2.5 formation it can be said that the emissions of NOx and SOx from RSEP do have the potential (if left unmitigated) to contribute to higher PM2.5 levels in the region; however, the region is designated unclassified/attainment for the PM2.5 standards and the low level of NOx and SOx emissions from the proposed project would not significantly impact that status.

Impact Summary

The applicant is proposing to mitigate the proposed project's stationary source NOx, VOC, SO₂, and PM10/PM2.5 emissions through the use of Best Available Control Technology (BACT). With the staff recommended mitigation measure for vehicle emissions, which is formalized in Staff Condition of Certification **AQ-SC6**, staff concludes that the proposed project would not cause significant secondary pollutant impacts.

CEQA LEVEL OF SIGNIFICANCE

Project Construction

Staff considers the unmitigated construction NOx, VOC, and PM emissions to be potentially CEQA significant and, therefore, staff is recommending that the NOx, VOC, and PM emission be mitigated pursuant to CEQA. Staff is recommending several mitigation measures (**AQ-SC1** through **AQ-SC5**), that include the applicant's proposed construction mitigation measures, to limit exhaust emissions and fugitive dust emissions during project construction to the extent feasible. Staff concurs with the District mitigation measures (**AQ-T1** through **AQ-T42**). These conditions limit exhaust emissions from temporary stationary sources during construction.

Therefore, while there would be adverse CEQA air quality impacts during construction, they are expected to be less than significant after implementation of the applicant's proposed and staff's recommended mitigation measures.

Salt System Commissioning

Staff considers the unmitigated salt system commissioning NOx, VOC, and PM emissions to be potentially CEQA significant and, therefore, staff is recommending that the NOx, VOC, and PM emissions be mitigated pursuant to CEQA. Staff concurs with the District mitigation measures (**AQ-T12** through **AQ-T42**). These conditions limit exhaust emissions and fugitive dust emissions during salt system commissioning through the required use of Best Available Control Technology and Best Management

Practices, they cover the salt handling and milling, the two heaters for salt melting and heating, and the NOx emissions from the salt conditioning.

Therefore, while there would be adverse CEQA air quality impacts during salt system commissioning, they are expected to be less than significant after implementation of the applicant's proposed and staff's and District's recommended mitigation measures.

Project Operation

Staff considers the unmitigated operation and maintenance NOx, VOC, and PM emissions to be potentially CEQA significant and, therefore, staff is recommending that the NOx, VOC, and PM emissions be mitigated pursuant to CEQA. Staff is recommending two mitigation measures (**AQ-SC6** and **AQ-SC7**), that also include the applicant's proposed operations emission mitigation measures, to limit exhaust emissions and fugitive dust emissions during project operation to the extent feasible.

Operation of the molten salt system involves routine venting to the atmosphere of the headspace in the molten salt storage tanks. Staff recommends **AQ-SC9** which requires a source test plan to quantify the NOx and PM emissions from the tank venting and an analysis to confirm that these emissions are negligible.

Staff concurs with the District mitigation measures (**AQ-1** through **AQ-29**). These conditions limit exhaust emissions from the permanent emission sources.

Therefore, while there would be adverse CEQA air quality impacts during operation, they are expected to be less than significant after implementation of the applicant's stipulated and staff's recommended mitigation measures.

Closure and Decommissioning

Eventually the facility would close, either at the end of its useful life or due to some unexpected situation such as a natural disaster or catastrophic facility breakdown. When the facility closes, all sources of air emissions would cease to operate and thus impacts associated with those emissions would no longer occur. The only other expected emissions would be equipment exhaust and fugitive particulate emissions from the dismantling activities. These activities would be of much a shorter duration than construction of the proposed project, equipment are assumed to have much lower comparative emissions due to technology advancement, and fugitive dust emissions would be required to be controlled in a manner at least equivalent to that required during construction. Therefore, while there would be adverse CEQA air quality impacts during decommissioning, they are expected to be less than significant.

REDUCED ACREAGE ALTERNATIVE

The Reduced Acreage Alternative would be 7.2% smaller in acreage than the proposed project. It would be located in the same 2,560-acre square-shaped parcel within the larger 3,324-acre ownership property as the proposed project. Although the overall heliostat field distance from the central tower would be reduced, the number of heliostats would remain the same. The heliostat field (plus the evaporation pond and administration areas) would occupy about 1,270 acres instead of the 1,370 acres required for the proposed project. The receiver location would remain the same, with the

edges of the field contracting towards the center. The heliostat footprint of the Reduced Acreage Alternative is shown in **Alternatives Figure 2**. The site layout, 653-foot total height of the solar tower and receiver, and transmission interconnection to Western's Parker-Blythe transmission line would be the same as the proposed project. The generation output would be reduced by approximately 2 MW (or 1.3%). Similar to the proposed project, the Reduced Acreage Alternative would transmit power to the grid through the planned Western substation to be located adjacent to Western's Parker-Blythe 161 kV transmission line.

The Reduced Acreage Alternative is evaluated in this SA/DEIS because it would eliminate about 100 acres of the proposed project footprint, reducing impacts to ephemeral washes, the loss of land considered habitat for the state and federally listed threatened desert tortoise and impacts to the historic Rice airfield. The Reduced Acreage Alternative would allow the applicant to contribute clean, renewable energy to help meet the State's energy goals, while minimizing impacts to the desert environment. A limited acreage alternative was suggested in scoping comments.

Under the Reduced Acreage Alternative, the agencies would approve a facility with a 7.2% heliostat field reduction and corresponding 148 MW generating capacity, not the 150 MW project that is proposed.

SETTING AND EXISTING CONDITIONS

The setting for the Reduced Acreage Alternative is the same as for the proposed project except that the heliostat field would occupy 1,270 acres within the 1,370-acre footprint of the proposed project. The existing ambient air quality does not change and the facility would still be within the same air basin and subject to the same air quality LORS.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

The Reconfigured Alternative would require approximately the same amount of construction and would have the same operating equipment and nearly identical operating maintenance requirements. The applicant did not provide criteria pollutant emission estimates for the construction and operation of this alternative but staff assumes that the construction and operation emissions are approximately the same or just slightly lower due to the reduction in heliostat construction area, as those for the proposed project. Therefore, the construction, salt commissioning and operation emissions would be similar to those shown in **Air Quality Tables 6 and 7**, **Air Quality Table 8** and **Air Quality Tables 9 and 10**, respectively.

The maximum daily and maximum annual construction and operation emissions and emission impacts for the Reconfigured Alternative are likely to be as high as that estimated for the proposed project, assuming the same maximum daily and annual construction activities, the same amount of salt conditioning, and the same number and type of stationary sources. Staff assumes that the incremental impact of the reconfigured project site would essentially be the same as the impacts estimated for the proposed project. Therefore, the worst-case short-term and annual construction and operation pollutant concentration impacts for this alternative are likely to be similar to those shown for the proposed project in **Air Quality Tables 11, 12 and 13**, respectively.

The results of the Reconfigured Alternative would be the following:

- The worst-case short-term construction emissions and ground level pollutant concentration impacts would be the same as the proposed project and would require the same level of mitigation. The total construction period and total construction emissions and long-term ground level pollutant concentration impacts would be similar to those required to construct the proposed project.
- The operation emissions and ground level pollutant concentration impacts would be essentially identical to the proposed project and would require the same level of mitigation.
- The benefits of the proposed project in displacing fossil fuel fired generation and reducing associated criteria pollutant emissions from fossil fuel-fired generation would be minimally reduced due to the 1.3% drop in generating capacity for this alternative.

NORTH OF DESERT CENTER ALTERNATIVE

The North of Desert Center Alternative would be a 150 MW solar thermal facility located on approximately 2,643 acres of land. It is located along Desert Center Rice Road (State Route 177) east of Kaiser Road, north of Oasis Road, and approximately 1.6 miles north of I-10 and is about 40 miles southwest of the applicant's proposed original site. The North of Desert Center Alternative is primarily private land with smaller sections of BLM land in the eastern portion of the site. It is largely fallow agricultural land. The existing SCE 161-kV transmission line (from the Blythe-2 substation to the Eagle Mountain-1 substation) that traverses the alternative site would be realigned to roughly follow the site boundary. A new 0.125-mile transmission line (along Osborne Ave.) and substation would interconnect to the realigned SCE line at the northeast boundary of the site. The boundaries and transmission realignment of the North of Desert Center Alternative are illustrated in **Alternatives Figure 3**.

The North of Desert Center Alternative is evaluated in this SA/DEIS because it would reduce impacts to cultural resources; the applicant-proposed RSEP is located on the historic Rice Army Airfield. This alternative would also reduce impacts to ephemeral washes and impacts associated with the loss of land considered habitat for the state and federally listed threatened desert tortoise. The North of Desert Center Alternative would allow the applicant to contribute clean, renewable energy to help meet the State's energy goals, while minimizing impacts to the desert environment.

SETTING AND EXISTING CONDITIONS

The setting for the North of Desert Center Alternative is different in certain ways from that of the proposed project. This alternative would be located within the same air basin, but would be under the jurisdiction of the South Coast Air Quality Management District (SCAQMD). The SCAQMD has different air quality regulations and requirements than the MDAQMD and is likely to require additional mitigation for this alternative in comparison with the proposed project. Specifically, the salt conditioning NO_x emissions, which are over the SCAQMD offset trigger of 4 tons per year, would require offsets to be obtained for the project. Currently, the quantity of NO_x emission reduction credits

available within the SCAQMD is extremely limited, so this permitting requirement would make this alternative very difficult if not impossible to permit.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

The North of Desert Center Alternative would require essentially the same amount of construction and would be assumed to have the same operating equipment and essentially identical operating maintenance requirements. Therefore, the construction, salt commissioning and operation emissions would be similar to those shown in **Air Quality Tables 6 and 7**, **Air Quality Table 8** and **Air Quality Tables 9 and 10**, respectively.

The maximum daily and maximum annual construction and operation emissions and emission impacts for the North of Desert Center Alternative are likely to be nearly the same as those estimated for the proposed project, assuming the same maximum daily and annual construction activities, the same amount of salt conditioning, and the same number and type of stationary sources during operation. There is some potential for differences due to different terrain, meteorological conditions and ambient background concentrations. As discussed in the Dispersion Modeling Assessment section, the applicant used the SCREEN3 meteorological data set for the screening assessment of the proposed project. These data are assumed to also be applicable to the North of Desert Center site. Therefore, staff assumed that the incremental impact of the North of Desert Center Alternative would essentially be the same as the impacts estimated for the proposed project and that the worst-case short-term and annual construction and operation pollutant concentration impacts for this alternative are likely to be similar to those shown for the proposed project in **Air Quality Tables 11, 12 and 13**, respectively.

The results of the North of Desert Center Alternative would be the following:

- The worst-case short-term construction emissions and ground level pollutant concentration impacts would be the similar to those determined for the proposed project and would require the same level of mitigation. The total construction period and total construction emissions and long-term ground level pollutant concentration impacts would be similar to those required to construct the proposed project.
- The operation emissions and ground level pollutant concentration impacts would be similar to those determined for the proposed project and would require the same level of mitigation.
- The benefits of displacing fossil fuel fired generation and reducing associated criteria pollutant emissions from fossil fuel-fired generation would be essentially identical to those of the proposed project.

If this site becomes the preferred site for this facility, these conclusions should be verified using site-specific analysis.

SR 62/RICE VALLEY ROAD GENERATION TIE LINE ALTERNATIVE

The SR 62/Rice Valley Road Generation Tie Line Alternative would interconnect to Western's 161-kV/230-kV Parker-Blythe transmission line at the same location as the proposed project transmission line. This alternative tie line would exit the power block

directly to the east and follow a proposed access road within the heliostat field. The tie-in would then turn north inside the RSEP property boundary and run along the RSEP's circular perimeter road to the north and northwest. At the north end of the heliostat field, the route would traverse the construction laydown area on previously disturbed land over a distance of approximately 500 feet to the southern side of State Route 62. The route would follow State Route 62 approximately 3.8 miles east to the junction of Rice Valley Road. It would then trend south to follow the unpaved Rice Valley Road for 4.1 miles to its juncture with the applicant's proposed new transmission line alignment and continue southeast for 5.4 miles along the proposed alignment to Western's Parker-Blythe transmission line. The SR 62/Rice Valley Road Transmission Line Alternative route is illustrated in **Alternatives Figure 4**.

The SR 62/Rice Valley Road Transmission Line Alternative is evaluated in this SA/DEIS because it would avoid the permanent loss of 13.4 acres of foraging and cover habitat for plant and animal species, including the state and federally listed threatened desert tortoise. This alternative would also avoid the creation of a new 4.6 mile vehicle access route between the proposed solar facility and the proposed junction of the new transmission line access road with the existing Rice Valley road. The proposed new vehicle access route would necessitate additional enforcement and maintenance to prevent unauthorized off-road vehicle access, propagation of new, unauthorized vehicle routes, and consequent habitat damage, soil erosion, and vehicle disturbance.

SETTING AND EXISTING CONDITIONS

The setting and existing conditions for this alternative are the same as the proposed project. The existing ambient air quality does not change and the facility would still be within the same air basin and subject to the same air quality LORS.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

The SR 62/Rice Valley Road Transmission Line Alternative would require essentially the same amount of construction and would be assumed to have the same operating equipment and essentially identical operating maintenance requirements. Therefore, the construction, salt commissioning and operation emissions would be similar to those shown in **Air Quality Tables 6 and 7**, **Air Quality Table 8** and **Air Quality Tables 9 and 10**, respectively.

The maximum daily and maximum annual construction and operation emissions and emission impacts for the SR 62/Rice Valley Road Transmission Line Alternative are likely to be nearly the same as those estimated for the proposed project. There is some potential for differences due to small differences in the transmission connection construction requirements. However, staff assumes that the incremental impact of the SR 62/Rice Valley Road Transmission Line Alternative would essentially be the same as the impacts estimated for the proposed project. Therefore, the worst-case short-term and annual construction and operation pollutant concentration impacts for this alternative are likely to be similar to those shown for the proposed project in **Air Quality Tables 11, 12 and 13**, respectively.

The results of the SR 62/Rice Valley Road Transmission Line Alternative would be the following:

- The worst-case short-term construction emissions and ground level pollutant concentration impacts would be the similar to those determined for the proposed project and would require the same level of mitigation. The total construction period and total construction emissions and long-term ground level pollutant concentration impacts would be similar to those required to construct the proposed project.
- The operation emissions and ground level pollutant concentration impacts would be identical to those determined for the proposed project and would require the same level of mitigation.
- The benefits of displacing fossil fuel fired generation and reducing associated criteria pollutant emissions from fossil fuel-fired generation would be identical to those of the proposed project.

NO PROJECT/NO ACTION ALTERNATIVE

No Project and No Action on Rice Solar Energy Project transmission line application and interconnection request. No CDCA land use plan amendment.

Under this alternative, the proposed Rice Solar Energy Project would not be approved by the Energy Commission; BLM would not approve the generation tie line ROW application and would not amend the CDCA Plan; and Western would not approve the interconnection request. As a result, no solar energy project would be constructed on the project site, BLM would continue to manage the land encompassing the transmission line consistent with the existing land use designation in the CDCA Land Use Plan of 1980, as amended, and Western would continue to operate the Parker-Blythe Transmission Line under current conditions.

Because there would be no amendment to the CDCA Plan and no solar project approved for the site under this alternative, it is expected that the site would continue to remain in its existing condition, with no new structures or facilities constructed or operated on the site. As a result, none of the direct air quality emission impacts from construction, salt conditioning, and operation from the proposed project would occur and none of the indirect Western States emission reduction benefits of the proposed project from displacing fossil-fuel fired generation would occur. In the absence of this project, other renewable energy projects may be constructed to meet State and Federal mandates⁵, and those projects would have similar impacts in other locations.

CUMULATIVE IMPACTS

Cumulative impacts are defined by CEQA as “two or more individual effects which, when considered together, are considerable or . . . compound or increase other environmental impacts.” (CEQA Guidelines, § 15355.) A cumulative impact consists of an impact that is created as a result of a combination of the project evaluated in the EIR together with other projects causing related impacts.” (CEQA Guidelines, §

⁵ Such as the State of California 33% Renewable Portfolio Standard (RPS) mandated under Executive Order S-14-08.

15130(a)(1).) Such impacts may be relatively minor and incremental, yet still be significant because of the existing environmental background, particularly when one considers other closely related past, present, and reasonably foreseeable future projects.

Cumulative effects are defined by the Council on Environmental Quality NEPA regulations as "...the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such actions" (40 CFR 1508.7).

This analysis is concerned with criteria air pollutants. Such pollutants have impacts that are usually (though not always) cumulative by nature. Rarely would a project by itself cause a violation of a federal or state criteria pollutant standard. However, a new source of pollution may contribute to violations of criteria pollutant standards because of the existing background sources or foreseeable future projects. Air districts attempt to attain the criteria pollutant standards by adopting attainment plans, which comprise a multi-faceted programmatic approach to such attainment. Depending on the air district, these plans typically include requirements for air offsets and the use of Best Available Control Technology (BACT) for new sources of emissions, and restrictions of emissions from existing sources of air pollution.

Thus, much of the preceding discussion is concerned with cumulative impacts. The "Existing Ambient Air Quality" subsection describes the air quality background in the Riverside County portion of the Mojave Desert Air Basin, including a discussion of historical ambient levels for each of the significant criteria pollutants. The "Construction Impacts and Mitigation" subsection discusses the proposed project's contribution to the local existing background caused by project construction. The "Operation Impacts and Mitigation" subsection discusses the proposed project's contribution to the local existing background caused by project operation. The following subsection includes two additional analyses:

- a summary of projections for criteria pollutants by the air district and the air district's programmatic efforts to abate such pollution⁶; and
- an analysis of the proposed project's *localized cumulative impacts*⁷, the proposed project's direct operating emissions combined with other local major emission sources.

SUMMARY OF PROJECTIONS

The Riverside County portion of the MDAB⁸ is designated as attainment or unclassified for all federal ambient air quality standards and the state CO, NO₂, SO₂ and PM_{2.5}

⁶ This cumulative impact assessment covers potential cumulative impacts to the entire air basin.

⁷ This cumulative impact assessment covers potential cumulative impacts near the project site, including potential cumulative impacts to receptors near the project site.

⁸ The project site is wholly within Riverside County but is adjacent to San Bernardino County. The area of San Bernardino County just north of the project site has the same federal and state attainment status as the project site within Riverside County except for the PM₁₀ NAAQS for which San Bernardino County is nonattainment and that portion of Riverside County is unclassified.

standards, but is designated as non-attainment for State ozone and PM10 standards. (See **Air Quality Table 3**)

Ozone

Since a portion of San Bernardino County in the Mojave Desert Air Basin, west northwest of the project site, is currently classified as non-attainment for the federal 8-hour ozone standard, the District is required to prepare and adopt an ozone attainment plan for submittal to the U.S. EPA describing how it will attain the federal 8-hour standard. The District completed this plan in 2008. The project is not specifically subject to the provisions in the federal attainment plan and the site is outside of the non-attainment area.

The District is required to prepare and adopt a state ozone attainment plan for submittal to ARB. The latest state ozone attainment plan was adopted by MDAQMD in 2004. The MDAQMD 2004 Ozone Attainment Plan contains attainment plans for both federal (for areas within San Bernardino County) and state ozone standards. The MDAQMD did not propose to adopt any additional control measures as part of the 2004 Plan. Additionally, while there are no additional control measures for direct ozone precursor reduction as part of the federal 2008 attainment plan, MDAQMD is committed to adopt all applicable Federal Reasonably Available Control Technology (RACT) rules that the MDAQMD proposed in the 8-hour Reasonably Available Control Technology – State Implementation Plan Analysis (RACT SIP Analysis) completed in 2006 (MDAQMD 2006). In addition, the MDAQMD updated and identified new measures in 2007, which will be adopted through 2014, as the State of California mandates all feasible measures. The RACT rules and other new measures do not impact the Rice Solar emission sources as proposed.

Particulate Matter

Since San Bernardino County is currently classified as non-attainment for the federal PM10 standards, the District is required to prepare and adopt an attainment plan for submittal to the U.S. EPA describing how it will achieve attainment with the federal PM10 standards. However, since the proposed project site is in Riverside County and is outside of the non-attainment area, the proposed project is not subject to the provisions in the federal attainment plan. There is no legal requirement for air districts to provide plans to attain the state PM10 standards, so air districts have not developed such plans. Therefore, there are no air quality management plan particulate emission control measures that are applicable to the proposed project.

As a solar power generation facility, the direct air pollutant emissions from power generation are negligible and the emission sources would be limited to auxiliary and emergency equipment and maintenance activities. The emissions from the proposed project would be minimal compared to other conventional fossil-fueled power generation facilities, and with staff's recommended construction and operation mitigation measures it is unlikely that the proposed project would have significant impact on particulate matter emissions.

Summary of Conformance with Applicable Air Quality Plans

The applicable air quality plan does not outline any new control measures applicable to the proposed project's operating emission sources. Therefore, compliance with existing District rules and regulations would ensure compliance with those air quality plans. However, there are several pending solar and wind projects in the Rice Valley area, in areas surrounding Rice Valley in Eastern Riverside or San Bernardino Counties, and surrounding the I-10 corridor area in Riverside County between Desert Center and Blythe (see **Table 3** and **Figure 2** in the **Cumulative Analysis Section**) including three thermal solar projects, the Blythe Solar Power Project, the Palen Solar Power Project, and the Genesis Solar Energy Project siting cases, which are currently being evaluated by the Energy Commission and BLM. Additionally there are a few other proposed projects including transmission projects and private developer projects (residential/landfill/racetrack) located in the general project area. This potential for significant additional development within the air basin and corresponding increase in air basin emissions is a major part of staff's rationale for recommending Conditions of Certification **AQ-SC6** and **AQ-SC7** that are designed to mitigate the proposed project's cumulative impacts by reducing the dedicated on-site vehicle emissions and fugitive dust emissions during site operation.

LOCALIZED CUMULATIVE IMPACTS

Since the power plant air quality impacts can be reasonably estimated through air dispersion modeling (see the "Operation Modeling Analysis" subsection) the proposed project's contributions to localized cumulative impacts can be estimated. To represent *past* and, to an extent, *present projects* that contribute to ambient air quality conditions, the Energy Commission staff recommends the use of ambient air quality monitoring data (see the "Existing Ambient Air Quality" subsection), referred to as the *background*. The staff takes the following steps to estimate what are additional appropriate "present projects" that are not represented in the background and "reasonably foreseeable projects":

- First, the Energy Commission staff (or the applicant) works with the air district to identify all projects that have submitted, within the last year of monitoring data, new applications for an authority to construct (ATC) or permit to operate (PTO) and applications to modify an existing PTO within six miles of the project site. Based on staff's modeling experience, beyond six miles there is no statistically significant concentration overlap for non-reactive pollutant concentrations between two stationary emission sources.
- Second, the Energy Commission staff (or the applicant) works with the air district and local counties to identify any new area sources within six miles of the project site. As opposed to point sources, area sources include sources like agricultural fields, residential developments or other such sources that do not have a distinct point of emission. New area sources are typically identified through draft or final Environmental Impact Reports (EIRs) that are prepared for those sources. The initiation of the EIR process is a reasonable basis on which to determine what is "reasonably foreseeable" for new area sources.
- The data submitted, or generated from the applications with the air district for point sources or initiating the EIR process for area sources, provides enough information

to include these new emission sources in air dispersion modeling. Thus, the next step is to review the available EIR(s) and permit application(s), determine what sources must be modeled and how they must be modeled.

- Sources that are not new, but may not be represented in ambient air quality monitoring are also identified and included in the analysis. These sources include existing sources that are co-located with or adjacent to the proposed source (such as an existing power plant). In most cases, the ambient air quality measurements are not recorded close to the proposed project, thus a local major source might not be well represented by the background air monitoring. When these sources are included, it is typically a result of there being an existing source on the project site and the ambient air quality monitoring station being more than two miles away.
- The modeling results must be carefully interpreted so that they are not skewed towards a single source, in high impact areas near that source's fence line. It is not truly a cumulative impact of Rice Solar if the high impact area is the result of high fence line concentrations from another stationary source and Rice Solar is not providing a substantial contribution to the determined high impact area.

Once the modeling results are interpreted, they are added to the background ambient air quality monitoring data and thus the modeling portion of the cumulative assessment is complete. Due to the use of air dispersion modeling programs in staff's cumulative impacts analysis, the applicant must submit a modeling protocol, based on information requirements for an application, prior to beginning the investigation of the sources to be modeled in the cumulative analysis. The modeling protocol is typically reviewed, commented on, and eventually approved in the Data Adequacy phase of the licensing procedure. Staff typically assists the applicant in finding sources (as described above), characterizing those sources, and interpreting the results of the modeling. However, the actual modeling runs are usually left to the applicant to complete. There are several reasons for this: modeling analyses take time to perform and require significant expertise, the applicant has already performed a modeling analysis of the proposed project alone (see the "Operation Modeling Analysis" subsection), and the applicant can act on its own to reduce stipulated emission rates and/or increase emission control requirements as the results warrant. Once the cumulative project emission impacts are determined, the necessity to mitigate the proposed project emissions can be evaluated, and the mitigation itself can be proposed by staff and/or the applicant (see the "Operation Mitigation" subsection).

The applicant, in consultation with MDAQMD, confirmed that there are no projects within a six miles radius from the Rice Solar project site that are under construction or have received permits to be built or operate in the foreseeable future. Therefore, it has been determined that no stationary sources requiring a cumulative modeling analysis exist within a six mile radius of the proposed project site. However, as noted previously there is the potential for the development of several solar and wind projects within or surrounding the Rice Valley or within the eastern MDAB that could eventually create cumulative air quality impacts if these projects are not adequately mitigated. This potential for significant additional development within the air basin and corresponding increase in air basin emissions is a major part of staff's rationale for recommending Conditions of Certification **AQ-SC6** and **AQ-SC7** that are designed to mitigate the proposed project's cumulative impacts by reducing the dedicated on-site vehicle

emissions and fugitive dust emissions during site operation. With these recommended CEQA-only mitigation measures, staff has concluded that the CEQA cumulative air quality impacts are less than significant.

Staff has considered the minority population surrounding the site (see **Socioeconomics Figure 1**). Since the proposed project's cumulative air quality impacts have been mitigated to less than significant, there is no environmental justice issue for air quality.

COMPLIANCE WITH LORS

The Mojave Desert Air Quality Management District issued the Preliminary Determination of Compliance (PDOC) for the RSEP on June 10, 2010 (MDAQMD 2010), and will issue a Final Determination of Compliance after a 30 day public notice period. Compliance with all District rules and regulations was demonstrated to the District's satisfaction in the PDOC. The District's PDOC conditions are presented in the Conditions of Certification (**AQ-1** to **AQ-29** for the permanent sources and **AQ-T1** to **AQ-T43** for the temporary sources).

Staff submitted an official PDOC comment letter and expects that the FDOC may contain revisions to conditions due to Energy Commission, applicant, or third party comments, and staff will provide a Staff Assessment addendum with any revised FDOC findings or conditions of certification.

FEDERAL

The District is responsible for issuing the federal New Source Review (NSR) permit and has been delegated enforcement of the applicable New Source Performance Standards. However, the proposed project does not require a federal NSR or Title V permit and would not require a PSD permit from U.S.EPA prior to initiating construction.

The proposed project requires the approval of a federal agency (BLM), but is located in an area that is in attainment or unclassified with all federal ambient air quality standards. Therefore, the proposed project is not subject to the general conformity regulations (40 CFR Part 93).

STATE

The project owner will demonstrate that the proposed project will comply with Section 41700 of the California State Health and Safety Code, which restricts emissions that would cause nuisance or injury, with the issuance of the District's Final Determination of Compliance and the Energy Commission's affirmative finding for the project.

The emergency generator and fire water pump engines are also subject to the Airborne Toxic Control Measure (ATCM) for Stationary Compression Ignition Engines. This measure limits the types of fuels allowed, establishes maximum emission rates, and establishes recordkeeping requirements. The proposed Tier 2 emergency generator engines and Tier 3 fire water pump engines meet the current emission limit requirements of this measure. This measure would also limit the engines' testing and maintenance operation to no more than 50 hours per year. Please note that the MDAQMD has proposed permit conditions specific to this project that would limit the

annual operating hours for testing and maintenance to no more than 26 hours per year per engine.

LOCAL

The District rules and regulations specify the emissions control and offset requirements for new sources such as the RSEP. Best Available Control Technology would be implemented, and emission reduction credits (ERCs) are not required to offset the proposed project's emissions by District rules and regulations based on the permitted stationary source emission levels for the proposed project. Compliance with the District's new source requirements would ensure that the proposed project would be consistent with the strategies and future emissions anticipated under the District's air quality attainment and maintenance plans.

The applicant provided an air quality permit application to the MDAQMD and the District issued a PDOC on June 10, 2010 (MDAQMD 2010). The PDOC states that the proposed project is expected to comply with all applicable District rules and regulations. The DOC evaluates whether and under what conditions the proposed project would comply with the District's applicable rules and regulations, as described below.

Regulation II – Permits

Rule 201 and 203 – Permit to Construct and Permit to Operate

Rule 201 establishes the emission source requirements that must be met to obtain a Permit to Construct. Rule 203 prohibits use or operation of any equipment which may emit air contaminants without first obtaining a Permit to Operate. The applicant has complied with this rule by submitting the AFC and District permit applications materials.

Regulation IV – Prohibitions

Rule 401 - Visible Emissions

This rule limits visible emissions from emissions sources, including stationary source exhausts and fugitive dust emission sources. Compliance with this rule is expected. In the PDOC, the District has determined that the facility is expected to comply with this rule.

Rule 402 - Nuisance

This rule restricts discharge of emissions that would cause injury, detriment, annoyance, or public nuisance. The facility is expected to comply with this rule (identical to California Health and Safety Code 41700).

Rule 403 - Fugitive Dust

This rule limits fugitive emissions from certain bulk storage, earthmoving, construction and demolition, and manmade conditions resulting in wind erosion. With the implementation of recommended staff conditions **AQ-SC3**, **AQ-SC4**, and **AQ-SC7** the facility is expected to comply with this rule.

Rule 404 - Particulate Matter Concentration

The rule limits particulate matter (PM) emissions based on the volume discharge rate. The RSEP stationary sources subject to this rule (emergency engines) would comply with the PM concentration limits of this regulation.

Rule 405 - Solid Particulate Matter Weight

This rule limits the discharge of solid particulate matter into the atmosphere based on the weight of material being processed. The salt handling and milling activities during the salt system commissioning would be subject to this rule. Compliance with this rule is expected.

Rule 406 - Specific Contaminants

The rule prohibits sulfur emissions, calculated as SO₂, in excess of 500 ppmv. Compliance with this rule is assured with the required use of pipeline quality natural gas for the boilers and heaters and California low sulfur diesel fuel for the emergency generator and fire pump engines.

Rule 407 - Liquid and Gaseous Air Contaminants

The rule prohibits carbon monoxide emissions in excess of 2,000 ppmv. The emergency generators and fire pump engines would have CO emissions well below this concentration limit. Compliance with this rule is expected.

Rule 409 - Fuel Burning Equipment - Combustion Contaminants

This rule limits discharge into the atmosphere from fuel burning equipment combustion contaminants exceeding in concentration at the point of discharge, 0.1 grain per cubic foot of gas calculated to 12% of carbon dioxide (CO₂) at standard conditions. The RSEP stationary sources would have particulate concentrations below limit of this rule.

Rule 431 - Sulfur Content of Fuels

The rule prohibits the burning of gaseous fuel with a sulfur content of more than 800 ppm and liquid fuel with a sulfur content of more than 0.5% sulfur by weight. Compliance with this rule is assured with the required use of pipeline quality natural gas and California low sulfur diesel fuel for the emergency engines.

Regulation IX – Standards of Performance for New Stationary Sources

Rule 900 – Standard of Performance for New Stationary Source (NSPS)

This rule incorporates the Federal NSPS (40 CFR 60) rules by reference. The District conditions would ensure compliance with the requirements of this rule.

The proposed Tier 2 and Tier 3 engines meet the current emission limit requirements of NSPS Subpart IIII that apply to the proposed RSEP equipment. The exact model and size of the engines are only estimated at this time. It is uncertain exactly when the emergency engines would be purchased and whether Tier 4 engine emission limits may apply at that time. District Conditions of Certification (**AQ-13** and **AQ-23**) require that the applicant comply with this NSPS standard.

Regulation XIII – New Source Review

Rule 1303 – New Source Review

This rule requires implementation of BACT for any emission source unit which emits or has the potential to emit 25 lbs/day or more and requires offsets if specific annual emission limits are exceeded. The PDOC concluded that the emergency engines trigger BACT and the engines complied. The other stationary sources did not trigger BACT but would meet BACT requirements based on the applicant's proposed controls. The PDOC concluded that offsets were not required for the proposed project.

Rule 1306 – Electric Energy Generating Facilities

Describes actions to be taken for permitting of power plants; Compliance with this rule would be achieved with the completion of the FDOC.

NOTEWORTHY PUBLIC BENEFITS

Renewable energy facilities, such as RSEP, are needed to meet California's mandated renewable energy goals. While there are no local area air quality public benefits⁹ resulting from the proposed project, it would indirectly reduce criteria pollutant emissions within the Southwestern U.S. by reducing fossil fuel fired generation.

CONCLUSIONS

Staff has made the following conclusions about the Rice Solar Energy Project:

- The proposed project would not have the potential to exceed PSD emission levels during direct source operation and the facility is not considered a major stationary source with potential to cause adverse air quality impacts.
- The proposed project would comply with applicable District Rules and Regulations and staff recommends the inclusion of the District's FDOC conditions as Conditions of Certification **AQ-1** through **AQ-29** for the permanent emission sources and Conditions of Certification **AQ-T1** through **AQ-T43** for the temporary emission sources.
- If left unmitigated, the proposed project's construction activities would likely contribute to significant CEQA adverse PM10 and ozone impacts. Staff recommends **AQ-SC1** to **AQ-SC5** to mitigate the potential impacts.
- The proposed project's operation would not cause new violations of any NO₂, SO₂, PM_{2.5} or CO ambient air quality standards. Therefore, the project-direct operation NO_x, SO_x, PM_{2.5} and CO emission impacts are not CEQA significant.
- The proposed project's direct and indirect (i.e., secondary) emissions contribution to existing violations of the ozone and PM10 ambient air quality standards are likely CEQA significant if unmitigated. Therefore, staff recommends **AQ-SC6** to mitigate the onsite maintenance vehicle emissions and **AQ-SC7** to mitigate the operating

⁹ Air quality benefits should not be confused with greenhouse gas/climate change benefits, which are discussed in Appendix AIR-1.

fugitive dust emissions to ensure that the potential ozone and PM10 CEQA impacts are mitigated to less than significant over the life of the project.

- Operation of the molten salt system involves routine venting to the atmosphere of the headspace in the molten salt storage tanks. Staff recommends **AQ-SC9** which requires a source test to quantify the NOx and PM emissions from the tank venting and an analysis to confirm that these emissions are negligible.
- The proposed project would be consistent with the requirements of SB 1368 and the Emission Performance Standard for greenhouse gases (see **Appendix Air-1**).

MITIGATION MEASURES/ PROPOSED CONDITIONS OF CERTIFICATION

The following Conditions of Certification meet the Energy Commission's responsibility to comply with the California Environmental Quality Act and serve as recommendations for the Energy Commission to consider in its decision to avoid or reduce the severity of impacts to less than significant and to assure conformance with LORS. The identification of relevant and reasonable mitigation measures also conforms to National Environmental Policy Act (NEPA) requirements for U.S. Bureau of Reclamation's (BLM's) and Western Area Power Administration's (Western's) analysis that can be considered in its Record of Decision.

STAFF CONDITIONS OF CERTIFICATION

Note that the term "CPM" refers to the Energy Commission's Compliance Project Manager.

AQ-SC1 Air Quality Construction Mitigation Manager (AQCMM): The project owner shall designate and retain an on-site AQCMM who shall be responsible for directing and documenting compliance with Conditions of Certification **AQ-SC3**, **AQ-SC4** and **AQ-SC5** for the entire project site and linear facility construction. The on-site AQCMM may delegate responsibilities to one or more AQCMM Delegates. The AQCMM and AQCMM Delegates shall have full access to all areas of construction on the project site and linear facilities, and shall have the authority to stop any or all construction activities as warranted by applicable construction mitigation conditions. The AQCMM and AQCMM Delegates may have other responsibilities in addition to those described in this condition. The AQCMM shall not be terminated without written consent of the Compliance Project Manager (CPM).

Verification: At least 30 days prior to the start of ground disturbance, the project owner shall submit to the CPM for approval, the name, resume, qualifications, and contact information for the on-site AQCMM and all AQCMM Delegates.

AQ-SC2 Air Quality Construction Mitigation Plan (AQCMP): The project owner shall provide an AQCMP, for approval, which details the steps that will be taken and the reporting requirements necessary to ensure compliance with Conditions of Certification **AQ-SC3**, **AQ-SC4**, and **AQ-SC5**.

Verification: At least 30 days prior to the start of any ground disturbance, the project owner shall submit the AQCMP to the CPM for approval. The AQCMP shall include effectiveness and environmental data for the proposed soil stabilizer. The CPM will notify the project owner of any necessary modifications to the plan within 15 days from the date of receipt.

AQ-SC3 Construction Fugitive Dust Control: The AQCMM shall submit documentation to the CPM in each Monthly Compliance Report that demonstrates compliance with the Air Quality Construction Mitigation Plan (AQCMP) mitigation measures for the purposes of minimizing fugitive dust emission creation from construction activities and preventing all fugitive dust plumes that would not comply with the performance conditions identified in **AQ-SC4** from leaving the project site. The following fugitive dust mitigation measures shall be included in the Air Quality Construction Mitigation Plan (AQCMP) required by **AQ-SC2**, and any deviation from the following mitigation measures shall require prior CPM notification and approval.

- a. The main access roads through the facility to the power block areas will be either paved or stabilized using soil binders, or equivalent methods, to provide a stabilized surface that is similar for the purposes of dust control to paving, that may or may not include a crushed rock (gravel or similar material with fines removed) top layer, prior to initiating construction in the main power block area, and delivery areas for operations materials (chemicals, replacement parts, etc.) will be paved or treated prior to taking initial deliveries.
- b. All unpaved construction roads and unpaved operation and maintenance site roads, as they are being constructed, shall be stabilized with a non-toxic soil stabilizer or soil weighting agent that can be determined to be both as efficient or more efficient for fugitive dust control as ARB approved soil stabilizers, and shall not increase any other environmental impacts including loss of vegetation to areas beyond where the soil stabilizers are being applied for dust control. All other disturbed areas in the project and linear construction sites shall be watered as frequently as necessary during grading (consistent with **BIO-7**); and after active construction activities shall be stabilized with a non-toxic soil stabilizer or soil weighting agent, or alternative approved soil stabilizing methods, in order to comply with the dust mitigation objectives of Condition of Certification **AQ-SC4**. The frequency of watering can be reduced or eliminated during periods of precipitation.
- c. No vehicle shall exceed 10 miles per hour on unpaved areas within the construction site, with the exception that vehicles may travel up to 25 miles per hour on stabilized unpaved roads as long as such speeds do not create visible dust emissions.
- d. Visible speed limit signs shall be posted at the construction site entrances.

- e. All construction equipment vehicle tires shall be inspected and washed as necessary to be cleaned free of dirt prior to entering paved roadways.
- f. Gravel or paved ramps of at least 20 feet in length must be provided at the tire washing/cleaning station.
- g. All unpaved exits from the construction site shall be graveled or treated to prevent track-out to public roadways.
- h. All construction vehicles shall enter the construction site through the treated entrance roadways, unless an alternative route has been submitted to and approved by the CPM.
- i. Construction areas adjacent to any paved roadway below the grade of the surrounding construction area or otherwise directly impacted by sediment from site drainage shall be provided with sandbags or other equivalently effective measures to prevent run-off to roadways, or other similar run-off control measures as specified in the Storm Water Pollution Prevention Plan (SWPPP), only when such SWPPP measures are necessary so that this condition does not conflict with the requirements of the SWPPP.
- j. All paved roads within the construction site shall be swept daily or as needed (less during periods of precipitation) on days when construction activity occurs to prevent the accumulation of dirt and debris.
- k. At least the first 500 feet of any paved public roadway exiting the construction site or exiting other unpaved roads en route from the construction site or construction staging areas shall be swept as needed (less during periods of precipitation) on days when construction activity occurs or on any other day when dirt or runoff resulting from the construction site activities is visible on the public paved roadways.
- l. All soil storage piles and disturbed areas that remain inactive for longer than 10 days shall be covered, or shall be treated with appropriate dust suppressant compounds.
- m. All vehicles that are used to transport solid bulk material on public roadways and that have potential to cause visible emissions shall be provided with a cover, or the materials shall be sufficiently wetted and loaded onto the trucks in a manner to provide at least two (2) feet of freeboard.
- n. Wind erosion control techniques (such as windbreaks, water, chemical dust suppressants, and/or vegetation) shall be used on all construction areas that may be disturbed. Any windbreaks installed to comply with this condition shall remain in place until the soil is stabilized or permanently covered with vegetation.

Verification: The AQCM shall provide the CPM a Monthly Compliance Report to include the following to demonstrate control of fugitive dust emissions:

- A. a summary of all actions taken to maintain compliance with this condition;
- B. copies of any complaints filed with the District in relation to project construction; and
- C. any other documentation deemed necessary by the CPM or AQCMM to verify compliance with this condition. Such information may be provided via electronic format or disk at the project owner's discretion.

AQ-SC4 Dust Plume Response Requirement: The AQCMM or an AQCMM Delegate shall monitor all construction activities for visible dust plumes. Observations of visible dust plumes that have the potential to be transported (A) off the project site and within 400 feet upwind of any regularly occupied structures not owned by the project owner or (B) 200 feet beyond the centerline of the construction of linear facilities indicate that existing mitigation measures are not resulting in effective mitigation. The AQCMP shall include a section detailing how the additional mitigation measures will be accomplished within the time limits specified. The AQCMM or Delegate shall implement the following procedures for additional mitigation measures in the event that such visible dust plumes are observed:

Step 1: The AQCMM or Delegate shall direct more intensive application of the existing mitigation methods within 15 minutes of making such a determination.

Step 2: The AQCMM or Delegate shall direct implementation of additional methods of dust suppression if Step 1, specified above, fails to result in adequate mitigation within 30 minutes of the original determination.

Step 3: The AQCMM or Delegate shall direct a temporary shutdown of the activity causing the emissions if Step 2, specified above, fails to result in effective mitigation within one hour of the original determination. The activity shall not restart until the AQCMM or Delegate is satisfied that appropriate additional mitigation or other site conditions have changed so that visual dust plumes will not result upon restarting the shutdown source. The owner/operator may appeal to the CPM any directive from the AQCMM or Delegate to shut down an activity, if the shutdown shall go into effect within one hour of the original determination, unless overruled by the CPM before that time.

Verification: The AQCMM shall provide the CPM a Monthly Compliance Report to include:

- A. a summary of all actions taken to maintain compliance with this condition;
- B. copies of any complaints filed with the District in relation to project construction; and
- C. any other documentation deemed necessary by the CPM or AQCMM to verify compliance with this condition. Such information may be provided via electronic format or disk at the project owner's discretion.

AQ-SC5 Diesel-Fueled Engine Control: The AQCMM shall submit to the CPM, in the Monthly Compliance Report, a construction mitigation report that

demonstrates compliance with the AQCMP mitigation measures for purposes of controlling diesel construction-related emissions. The following off-road diesel construction equipment mitigation measures shall be included in the Air Quality Construction Mitigation Plan (AQCMP) required by **AQ-SC2**, and any deviation from the following mitigation measures shall require prior CPM notification and approval.

- a. All diesel-fueled engines used in the construction of the facility shall have clearly visible tags issued by the on-site AQCM showing that the engine meets the conditions set forth herein.
- b. All construction diesel engines with a rating of 50 hp or higher shall meet, at a minimum, the Tier 3 California Emission Standards for Off-Road Compression-Ignition Engines, as specified in California Code of Regulations, Title 13, section 2423(b)(1), unless a good faith effort to the satisfaction of the CPM that is certified by the on-site AQCM demonstrates that such engine is not available for a particular item of equipment. In the event that a Tier 3 engine is not available for any off-road equipment larger than 50 hp, that equipment shall be equipped with a Tier 2 engine, or an engine that is equipped with retrofit controls to reduce exhaust emissions of nitrogen oxides (NOx) and diesel particulate matter (DPM) to no more than Tier 2 levels unless certified by engine manufacturers or the on-site AQCM that the use of such devices is not practical for specific engine types. For purposes of this condition, the use of such devices is “not practical” for the following, as well as other, reasons.
 1. There is no available retrofit control device that has been verified by either the California Air Resources Board or U.S. Environmental Protection Agency to control the engine in question to Tier 2 equivalent emission levels and the highest level of available control using retrofit or Tier 1 engines is being used for the engine in question; or
 2. The construction equipment is intended to be on site for 10 days or less.
 3. The CPM may grant relief from this requirement if the AQCM can demonstrate a good faith effort to comply with this requirement and that compliance is not practical.
- c. The use of a retrofit control device may be terminated immediately, provided that the CPM is informed within 10 working days of the termination and that a replacement for the equipment item in question meeting the controls required in item “b” occurs within 10 days of termination of the use, if the equipment would be needed to continue working at this site for more than 15 days after the use of the retrofit control device is terminated, if one of the following conditions exists :
 1. The use of the retrofit control device is excessively reducing the normal availability of the construction equipment due to increased down time for maintenance, and/or reduced power output due to an excessive

- increase in back pressure.
2. The retrofit control device is causing or is reasonably expected to cause engine damage.
 3. The retrofit control device is causing or is reasonably expected to cause a substantial risk to workers or the public.
 4. Any other seriously detrimental cause which has the approval of the CPM prior to implementation of the termination.
- d. All heavy earth-moving equipment and heavy duty construction-related trucks with engines meeting the requirements of (b) above shall be properly maintained and the engines tuned to the engine manufacturer's specifications.
 - e. All diesel heavy construction equipment shall not idle for more than five (5) minutes. Vehicles that need to idle as part of their normal operation (such as concrete trucks) are exempted from this requirement.
 - f. Construction equipment will employ electric motors when feasible.

Verification: The AQCMM shall include in the Monthly Compliance Report the following to demonstrate control of diesel construction-related emissions:

- A. A summary of all actions taken to control diesel construction-related emissions;
- B. A list of all heavy equipment used on site during that month, including the owner of that equipment and a letter from each owner indicating that equipment has been properly maintained; and
- C. Any other documentation deemed necessary by the CPM or AQCMM to verify compliance with this condition. Such information may be provided via electronic format or disk at the project owner's discretion.

AQ-SC6 The project owner, when obtaining dedicated on-road or off-road vehicles for mirror washing activities and other facility maintenance activities, shall only obtain vehicles that meet California on-road vehicle emission standards or appropriate U.S.EPA/California off-road engine emission standards for the latest model year available when obtained.

Verification: At least 30 days prior to the start of commercial operation, the project owner shall submit to the CPM a copy of the plan that identifies the size and type of the on-site vehicle and equipment fleet and the vehicle and equipment purchase orders and contracts and/or purchase schedule. The plan shall be updated every other year and submitted in the Annual Compliance Report.

AQ-SC7 The project owner shall provide a site Operations Dust Control Plan, including all applicable fugitive dust control measures identified in the verification of **AQ-SC3** that would be applicable to minimizing fugitive dust emission creation from operation and maintenance activities and preventing all fugitive

dust plumes that would not comply with the performance standards identified in **AQ-SC4** from leaving the project site; that:

- A. describes the active operations and wind erosion control techniques such as windbreaks and chemical dust suppressants, including their ongoing maintenance procedures, that shall be used on areas that could be disturbed by vehicles or wind anywhere within the project boundaries; and
- B. identifies the location of signs throughout the facility that will limit traveling on unpaved portion of roadways to solar equipment maintenance vehicles only. In addition, vehicle speed shall be limited to no more than 10 miles per hour on these unpaved roadways, with the exception that vehicles may travel up to 25 miles per hour on stabilized unpaved roads as long as such speeds do not create visible dust emissions.

The site Operations Fugitive Dust Control Plan shall include the use of durable non-toxic soil stabilizers on all regularly used unpaved roads and disturbed off-road areas, or alternative methods for stabilizing disturbed off-road areas, within the project boundaries, and shall include the inspection and maintenance procedures that will be undertaken to ensure that the unpaved roads remain stabilized. The soil stabilizer used shall be a non-toxic soil stabilizer or soil weighting agent that can be determined to be both as efficient, or more efficient for fugitive dust control as ARB-approved soil stabilizers, and shall not increase any other environmental impacts including loss of vegetation to areas beyond where the soil stabilizers are being applied for dust control.

The performance and application of the fugitive dust controls shall also be measured against and meet the performance requirements of condition **AQ-SC4**. The measures and performance requirements of **AQ-SC4** shall also be included in the operations dust control plan.

Verification: At least 30 days prior to start of commercial operation, the project owner shall submit to the CPM for review and approval a copy of the site Operations Dust Control Plan that identifies the dust and erosion control procedures, including effectiveness and environmental data for the proposed soil stabilizer, that will be used during operation of the project and that identifies all locations of the speed limit signs. Within 60 days after commercial operation, the project owner shall provide to the CPM a report identifying the locations of all speed limit signs, and a copy of the project employee and contractor training manual that clearly identifies that project employees and contractors are required to comply with the dust and erosion control procedures and on-site speed limits.

AQ-SC8 The project owner shall provide the CPM copies of all District issued Authority-to-Construct (ATC) and Permit-to-Operate (PTO) documents for the facility.

The project owner shall submit to the CPM for review and approval any modification proposed by the project owner to any project federal air permit. The project owner shall submit to the CPM any modification to any federal air

permit proposed by the District or U.S. Environmental Protection Agency (U.S. EPA), and any revised federal air permit issued by the District or U.S. EPA, for the project.

Verification: The project owner shall submit any ATC, PTO, and proposed federal air permit modifications to the CPM within 5 working days of its submittal either by 1) the project owner to an agency, or 2) receipt of proposed modifications from an agency. The project owner shall submit all modified ATC/PTO documents and all federal air permits to the CPM within 15 days of receipt.

AQ-SC9 The project owner shall perform source testing on the two molten salt tanks, at the vents, within the tank headspace or at other locations to be determined, within one year of the start of commercial operation to confirm that the emissions of NO_x from salt decomposition and particulate salt fume emissions from these tanks are negligible (defined for the purposes of this condition as, for each pollutant, less than 0.1 lbs/day, or the detection limits of the approved source test methodologies if higher). In the event that the source tests establish that the emissions of either or both of these pollutants are not negligible then the applicant shall establish emission factors for use to determine annual emissions that shall be reported in the annual compliance reports.

Verification: The project owner shall submit a molten salt tank NO_x and particulate source test plan for review and approval to the CPM at least 60 days prior to conducting the source tests. The source testing plan shall rely, to the extent practical, on existing USEPA/CARB source test methods and shall include the following information:

1. The proposed source test methods and their technical descriptions and proposed source sampling locations.
2. The proposed facility operating parameters and time of day for the tests. These source tests should be performed during periods of maximum tank venting emissions potential.
3. The proposed operating parameter (heat input, tank temperature, salt pumping rates, etc.) recordkeeping that will accompany the source test data.

The project owner shall provide the source test report as well as any determined salt tank emission factors to the CPM for review and approval within 60 days of the completion of the source tests.

DISTRICT CONDITIONS

DISTRICT PRELIMINARY DETERMINATION OF COMPLIANCE CONDITIONS (MDAQMD 2010)

The District Conditions of Certification are based on the Preliminary Determination of Compliance (PDOC) for the Rice Solar Energy Project issued by the Mojave Desert Air Quality Management District (MDAQMD) on June 10, 2010. The MDAQMD will accept public comments on the PDOC through July 19, 2010, after which the MDAQMD will issue a Final Determination of Compliance (FDOC). After the

MDAQMD issues the FDOC, staff will revise the following District conditions as appropriate.

The PDOC contains conditions applicable to the entire facility, permanent emission sources and temporary emission sources. The following District conditions are organized based on that grouping. Condition **AQ-1** is for the facility and covers both permanent and temporary emission sources. Condition **AQ-2** is for the facility and covers temporary emission sources. Conditions **AQ-3** through **AQ-29** cover the permanent emission sources. Conditions **AQ-T1** through **AQ-T43** cover the temporary emission sources.

District condition AQ-1 applies to the entire facility and covers both permanent and temporary emission sources.

AQ-1 The owner of this facility must submit an accurate emissions inventory data to the District, in a format approved by the District, on a yearly basis, which is to be received by the District no later than April 30 of each year.

Facility Calendar Year Emissions shall be less than the following:

PM10: 15 tpy
NOx: 25 tpy
SOx: 25 tpy
ROC: 25 tpy

Verification: As part of the Annual Compliance Report the project owner shall include information on operating emission rates to demonstrate compliance with this condition.

District condition AQ-2 applies to the entire facility and covers only temporary emission sources.

AQ-2 This entire facility shall not emit more than 9.9 t/y of a single HAP and not more than 24.9 t/y of all HAP's. To ensure compliance, the owner/operator shall calculate and record the annual emissions of Federal Hazardous Air Pollutants (HAP's) in tons per year (t/y) on a calendar year basis (January 1 through December 31). The list of HAP's can be found in Section 112(b)(1) of the Federal Clean Air Act or at web site: <http://www.epa.gov/ttn/atw/188polls.html>

Verification: As part of the Annual Compliance Report the project owner shall include information on operating emission rates to demonstrate compliance with this condition.

District conditions AQ-3 through AQ-29 apply to the permanent emission sources.

District conditions AQ-3 to AQ-13 apply to the following equipment permits:

Permit No. E010812 and E010813 (Two (2) Emergency Fire Water Pumps; rated at 600 BHP each)

EQUIPMENT DESCRIPTION:

Caterpillar, Model C18 Dita (or equivalent), a CARB Certified Tier 3 engine, serial number unknown, Year of manufacture unknown, 600 bhp, Turbo Charged, After Cooled, operating at 1750 rpm, fueled on CARB diesel, with a maximum rated fuel consumption of 31.4 gallons per hour, each powering a Fire Pump.

AQ-3 This system shall be installed, operated and maintained in strict accord with those recommendations of the manufacturer/supplier and/or sound engineering principles, which produce the minimum emissions of contaminants. Unless otherwise noted, this equipment shall also be operated in accordance with all data and specifications submitted with the application for this permit.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-4 Each engine may operate in response to notification of impending rotating outage if the area utility has ordered rotating outages in the area where the engines are located or expects to order such outages at a particular time, the engines are located in the area subject to the rotating outage, the engines are operated no more than 30 minutes prior to the forecasted outage, and the engines are shut down immediately after the utility advises that the outage is no longer imminent or in effect.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-5 Each engine may operate in response to fire suppression requirements and needs.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-6 Each unit shall only be fired on ultra-low sulfur diesel fuel, whose sulfur concentration is less than or equal to 0.0015% (15) on a weight per weight basis per CARB Diesel or equivalent requirements.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-7 This facility shall not perform testing of more than one Emergency internal combustion engine at a time.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-8 A non-resettable four-digit (9,999) hour timer shall be installed and maintained on each unit to indicate elapsed engine operating time. (17 CCR §93115(e)(4)(G)1).

Verification: At least 30 days prior to the installation of the engine, the project owner shall provide the District and the CPM the specification of the hour timer.

AQ-9 Each unit shall be limited to use for emergency power, defined as in response to a fire or when commercially available power has been interrupted or may be interrupted per **AQ-4**. In addition, this unit shall be operated no more than 26 hours per year, no more than thirty (30) minutes per day for testing and maintenance, excluding compliance source testing. Time required for source testing will not be counted toward the 26 hour per year limit.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-10 The 30-minute limit of **AQ-9** can be exceeded when the emergency fire pump assemblies are driven directly by the stationary diesel fueled CI engine when operated per and in accord with the National Fire Protection Association (NFPA) 25 - "Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems," 2006 edition or the most current edition approved by the CARB Executive Officer. {Title 17 CCR 93115(c)16}

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-11 The project owner shall maintain a operations log for each unit current and on-site (or at a central location) for a minimum of five (5) years, with records kept on-site for two (2) years, and be provided to District, State and Federal personnel upon request. The log shall include, at a minimum, the information specified below:

- a. Date of each use and duration of each use (in hours);
- b. Reason for use (testing & maintenance, emergency, required emission testing);
- c. Calendar year operation in terms of fuel consumption (in gallons) and total hours; and,
- d. Fuel sulfur concentration (the project owner may use the supplier's certification of sulfur content if it is maintained as part of this log).
- e. Documentation of maintenance as per manufacturer's recommendations and good maintenance practices.

Verification: The project owner shall submit records required by this condition that demonstrating compliance with the sulfur content and engine use limitations of conditions **AQ-6** and **AQ-9** in the Annual Compliance Report, including a photograph showing the annual reading of engine hours. The project owner shall make the site

available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-12 Each fire protection unit is subject to the requirements of the Airborne Toxic Control Measure (ATCM) for Stationary Compression Ignition Engines (Title 17 CCR 93115). In the event of conflict between these conditions and the ATCM, the more stringent requirements shall govern.

Verification: The project owner shall submit the engine specifications at least 30 days prior to purchasing the engines for review and approval demonstrating that the engines meet ATCM emission limit requirements at the time of engine purchase.

AQ-13 Each unit is subject to the requirements of the Federal New Source Performance Standards (NSPS) for Stationary Compression Ignition Internal Combustion Engines (40 CFR Part 60 Subpart IIII).

Verification: The project owner shall submit the engine specifications at least 30 days prior to purchasing the engines for review and approval demonstrating that the engines meet NSPS emission limit requirements at the time of engine purchase.

District conditions AQ-14 to AQ-23 apply to the following equipment permits:

Permit No. E010814 and E010815 (Two (2) Emergency Generators; rated at 4020 BHP each)

EQUIPMENT DESCRIPTION:

Caterpillar, Model C175-16 (or equivalent), a CARB Certified Tier 2 engine, serial number unknown, year of manufacture unknown, 4020 bhp, Turbo Charged, After Cooled, operating at **TBD** rpm, fueled on CARB diesel with a maximum rated fuel consumption of 213.3 gallons per hour, powering an electrical generator.

AQ-14 This equipment shall be installed, operated and maintained in strict accord with those recommendations of the manufacturer/supplier and/or sound engineering principles which produce the minimum emissions of contaminants. Unless otherwise noted, this equipment shall also be operated in accordance with all data and specifications submitted with the application for this permit.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-15 Each engine may operate in response to notification of impending rotating outage if the area utility has ordered rotating outages in the area where the engine is located or expects to order such outages at a particular time, the engine is located in the area subject to the rotating outage, the engine is operated no more than 30 minutes prior to the forecasted outage, and the engine is shut down immediately after the utility advises that the outage is no longer imminent or in effect.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-16 Each unit shall only be fired on ultra-low sulfur diesel fuel, whose sulfur concentration is less than or equal to 0.0015% (15ppm) on a weight per weight basis per CARB Diesel or equivalent requirements.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-17 A non-resettable four-digit (9,999) hour timer shall be installed and maintained on each unit to indicate elapsed engine operating time.

Verification: At least 30 days prior to the installation of the engine, the project owner shall provide the District and the CPM the specification of the hour timer.

AQ-18 This facility shall not perform testing of more than one Emergency internal combustion engine at a time.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-19 Each unit shall be limited to use for emergency power, defined as in response to a fire or when commercially available power has been interrupted or may be interrupted per **AQ-15**. In addition, this unit shall be operated no more than 26 hours per year, and no more than one (1) hour per day for testing and maintenance, excluding compliance source testing. Time required for source testing will not be counted toward the 26 hour per year limit.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-20 The project owner shall maintain a operations log for each unit current and on-site (or at a central location) for a minimum of five (5) years, with records kept on-site for two (2) years, and be provided to District, State and Federal personnel upon request. The log shall include, at a minimum, the information specified below:

- a. Date of each use and duration of each use (in hours);
- b. Reason for use (testing & maintenance, emergency, required emission testing);
- c. Calendar year operation in terms of fuel consumption (in gallons) and total hours; and,
- d. Fuel sulfur concentration (the project owner may use the supplier's certification of sulfur content if it is maintained as part of this log).
- e. Documentation of maintenance as per manufacturer's recommendations and good maintenance practices.

Verification: The project owner shall submit records required by this condition that demonstrating compliance with the sulfur content and engine use limitations of

conditions **AQ-16** and **AQ-19** in the Annual Compliance Report , including a photograph showing the annual reading of engine hours. The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-21 Each genset is subject to the requirements of the Airborne Toxic Control Measure (ATCM) for Stationary Compression Ignition Engines (Title 17 CCR 93115). In the event of conflict between these conditions and the ATCM, the more stringent requirements shall govern.

Verification: The project owner shall submit the engine specifications at least 30 days prior to purchasing the engines for review and approval demonstrating that the engines meet ATCM emission limit requirements at the time of engine purchase.

AQ-22 Each unit shall not be used to provide power during a voluntary agreed to power outage and/or power reduction initiated under an Interruptible Service Contract (ISC); Demand Response Program (DRP); Load Reduction Program (LRP) and/or similar arrangement(s) with the electrical power supplier.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-23 Each unit is subject to the requirements of the Federal New Source Performance Standards (NSPS) for Stationary Compression Ignition Internal Combustion Engines (40 CFR Part 60 Subpart IIII).

Verification: The project owner shall submit the engine specifications at least 30 days prior to purchasing the engines for review and approval demonstrating that the engines meet NSPS emission limit requirements at the time of engine purchase.

District conditions AQ-24 to AQ-29 apply to the following equipment permit:

Permit No. B010889 (Wet Surface Air Cooler (WSAC))

EQUIPMENT DESCRIPTION:

Manufacturer, and model **TBD**; system shall be equipped with drift elimination system rated at 0.0005%.

AQ-24 Operation of this equipment shall be conducted in compliance with all data and specifications submitted with the application under which this permit is issued unless otherwise noted below.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-25 This equipment shall be operated and maintained in strict accord with the recommendations of its manufacturer or supplier and/or sound engineering principles.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-26 The drift rate shall not exceed 0.0005% of the maximum circulation rate. The vendor performance specifications will be provided prior to the installation of this unit.

Verification: The manufacturer guarantee data for the drift eliminator, showing compliance with this condition, shall be provided to the CPM and the District 30 days prior to WSAC operation. As part of the Annual Compliance Report the project owner shall include information on operating emission rates to demonstrate compliance with this condition.

AQ-27 The project owner shall conduct water quality testing for total dissolved solids content for the WSAC recirculation water at least once per calendar quarter when the unit is operated.

Verification: The cooling tower recirculation water TDS content test results shall be provided to representatives of the District, ARB, and the Energy Commission upon request.

AQ-28 The project owner shall estimate annual PM₁₀ emissions from this unit using the quarterly water quality testing data and the WSAC design specifications for drift and recirculation rate. Facility calendar year PM₁₀ emissions shall be less than the PM₁₀ offset threshold of 15 ton per year.

Verification: The project owner shall provide an emissions calculation and water sample testing protocol to the District for approval and CPM for review at least 30 days prior to the first WSAC water test.

AQ-29 A log shall be kept of all inspections, repairs, and maintenance on equipment. This log shall be maintained current and on-site for a minimum of five (5) years, and be provided to District, State and Federal personnel upon request.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

District conditions AQ-T1 through AQ-T43 apply to the temporary (i.e., construction) emission sources.

Temporary conditions AQ-T1 to AQ-T10 apply to the following equipment permits:

Permit Nos. B010803, B010804, B0010806, and B0010807

Four (4) Diesel Powered Electrical Generators; each rated at 98 BHP

EQUIPMENT DESCRIPTION:

Isuzu (or Equivalent) Model BI-4HK1X (or Equivalent), serial number unknown, Year of manufacture unknown, Certified Tier 3 Engine, CARB Executive Order U-R-006-0285, Family 8SZXL03.0JXB 98 bhp, Direct Injected, Turbo Charged, After Cooled, Inter

Cooled, operating at unknown rpm, fueled on CARB diesel, with a maximum rated fuel consumption of 4.3 gallons per hour, powering an Electrical Generator.

Permit Nos. B010808, B010809, B010810, and B010811

Four (4) Diesel IC Engines; each rated at 173 BHP

EQUIPMENT DESCRIPTION:

Isuzu (or Equivalent) Model BI-4HK1X (or Equivalent), serial number unknown, Year of manufacture unknown, Certified Tier 3 Engine, CARB Executive Order U-R-006-0273, Family 8SZXL05.21 X B. 173 bhp, Direct Injected, Turbo Charged, After Cooled, Inter Cooled, operating at unknown rpm, fueled on CARB diesel, with a maximum rated fuel consumption of 7.3 gallons per hour.

AQ-T1 All equipment shall be installed, operated and maintained in strict accord with those recommendations of the manufacturer/supplier and/or sound engineering principles which produce the minimum emissions of contaminants. Unless otherwise noted, all equipment shall also be operated in accordance with all data and specifications submitted with the application for this permit.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T2 All equipment shall only be fired on ultra-low sulfur diesel fuel, with sulfur concentration less than or equal to 0.0015% (15 ppm) on a weight per weight basis per CARB Diesel or equivalent requirements. (17 CCR §93115(e)(1)(A))

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T3 A non-resettable four-digit (9,999) hour timer shall be installed and maintained on each unit to indicate elapsed engine operating time. (17 CCR §93115(e)(4)(G)1.)

Verification: At least 30 days prior to the installation of each engine, the project owner shall provide the District and the CPM the specification of the hour timer.

AQ-T4 The project owner shall maintain an operations log for each unit current and on-site for two (2) years, and be provided to District, State and Federal personnel upon request. The log shall include, at a minimum, the information specified below:

- a. Monthly hours of use (in hours) for each engine; total calendar year hours of operation for all four engines combined covered by **AQ-T11**, and total calendar year hours of operation for all four engines combined covered by **AQ-T12**;
- b. Calendar year operation in terms of fuel consumption (in gallons) and total hours; and,
- c. Fuel sulfur concentration (the project owner may use the supplier's certification of sulfur content if it is maintained as part of this log).

Verification: The project owner shall submit records required by this condition demonstrating compliance with the fuel sulfur content limitations of condition **AQ-T2** and the engine use limitations of conditions **AQ-T11** and **AQ-T12** in the Annual Compliance Report, including a photograph showing the annual reading of engine hours for each engine. The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T5 Pursuant to the Diesel ATCM section (17 CCR §93115(e)(1)(D)1.a.), Diesel Particulate Matter (DPM) emission from each ICE diesel equipment unit shall emit no more than 0.01 g/Bhp-hr or 85% reduction from Tier 3 emission levels for DPM at the time of installation.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T6 Each diesel fired ICE is subject to the requirements of the Airborne Toxic Control Measure (ATCM) for Stationary Compression Ignition Engines (17 CCR 93115). In the event of conflict between these Conditions and the ATCM, the more stringent requirements shall govern.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T7 Each engine shall not operate unless the exhaust is vented through a properly functioning Diesel Particulate trap.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T8 Each engine shall not operate unless equipped with a Verified Level 3 Control Device for 85%+ Diesel Particulate Reduction consistent with **AQ-T5** above. At present this add on control device has not been identified. Once information is available it shall be communicated to the District for incorporation into this Permit.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T9 All engines shall not be operated once line power is available to replace the electrical demand supported by such engine, and shall be removed from the site within 60 days of connection completion. The owner/operator shall request permit cancelation concurrent with engine removal.

Verification: The project owner shall submit to the CPM as part of the last Monthly Compliance Report or within 30 days of equipment removal confirmation of the date of equipment removal in compliance with the requirements of this condition. The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T10 These engines are subject to the requirements of the Federal New Source Performance Standards (NSPS) for Stationary Compression Ignition Internal Combustion Engines (40 CFR Part 60 Subpart IIII).

Verification: The project owner shall submit the engine specifications at least 30 days prior to purchasing or leasing the engines for review and approval demonstrating that the engines meet NSPS applicable emission limit requirements.

Temporary condition AQ-T11 applies to the following equipment permits:

Permit Nos. B010803, B010804, B0010806, and B0010807 (Four (4) Diesel Powered Electrical Generators; each rated at 98 BHP)

AQ-T11 The aggregated total hours accumulated from engines permitted as; B010803, B010804, B0010806 and B0010807 shall not exceed a combined total of 11,440 hours in any single calendar year period.

Verification: As part of the Annual Compliance Report the project owner shall include information on operating hours to demonstrate compliance with this condition.

Temporary condition AQ-T12 applies to the following equipment permits:

Permit Nos. B010808 and B010809, B010810, and B010811 (Four (4) Diesel IC Engines; each rated at 173 BHP each)

AQ-T12 The aggregated total hours accumulated from engines permitted as; B010808, B010809, B010810, and B010811 shall not exceed a combined total of 22,200 hours in any single calendar year period.

Verification: As part of the Annual Compliance Report the project owner shall include information on operating hours to demonstrate compliance with this condition.

Temporary conditions AQ-T13 to AQ-T22 applies to the following equipment permit:

Permit Nos. B010848 (Salt Handling System, Temporary)

EQUIPMENT DESCRIPTION:

Material handling and mixing equipment, enclosed mechanical screw conveyor located in an enclosed building and vented through a fabric filter baghouse.

AQ-T13 This equipment shall be properly maintained and kept in good operating condition in strict accord with the recommendations of the manufacturer/supplier and/or sound engineering principles.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T14 Operation of this equipment shall be conducted in compliance with all data and specifications submitted with the application under which this permit is issued unless otherwise noted below.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T15 This equipment and associated operations shall not discharge an exhaust stream that exhibits opacity greater than 20% (Ringelmann 1).

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T16 This equipment shall not be operated unless vented through properly functioning air pollution control equipment under valid District permit C010850.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T17 This equipment shall not process more than 480 tons of material in any one day and a total of 35,000 tons of product during the salt commissioning period.

Verification: The project owner shall submit to the CPM records on the amount of material processed on a daily basis to demonstrate compliance with this condition as part of the Annual Operation Report.

AQ-T18 The project owner shall maintain a log of all material throughput amounts so as to verify compliance with **AQ-T17**. Additionally, a log shall be kept of all inspections, repairs, and maintenance on equipment. Such logs or records shall be maintained at the facility for two (2) years, and be provided to District, State and Federal personnel upon request.

Verification: The project owner shall submit records required by this condition to demonstrate compliance with processing limitations condition **AQ-T17** in the Monthly Compliance Report. The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T19 The project owner shall maintain this equipment in strict accord with those recommendations of the manufacturer/supplier and/or sound engineering principles which produce the minimum emissions of air contaminants.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T20 All open material transfer points, such as conveyor drops, hopper and bin loading, shall be operated to minimize emissions of particulate matter.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-T21 The Owner/Operator shall maintain the equipment to preclude violations of District rules 401, 402 and 403.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-T22 Salt blending and commissioning operations are temporary and expected to be in service 24 hours per day, and up to 140 days during the salt system

commissioning phase. Subsequently, the salt milling and handling equipment shall be removed from the site within 60 days subsequent to power plant start up.

Verification: As part of the Monthly Compliance Report the project owner shall include information as required by **AQ-T18** to demonstrate compliance with this condition and shall submit as part of the last Monthly Compliance Report or within 30 days of equipment removal confirmation of the date of equipment removal in compliance with the requirements of this condition.

Temporary conditions AQ-T23 to AQ-T30 apply to the following equipment permits:

Permit No. B010792 (Heater, Salt Commissioning, Temporary)

EQUIPMENT DESCRIPTION:

Manufacturer **TBD** Model **TBD**, Serial Number **TBD** with a maximum heat input of 20 MMBtu/hr, equipped with Burner Model **TBD**.

Permit No. B010801 (Heater, Salt Commissioning, Temporary)

EQUIPMENT DESCRIPTION:

Manufacturer **TBD** Model **TBD**, Serial Number **TBD** with a maximum heat input of 55 MMBtu/hr, equipped with Burner Model **TBD**.

AQ-T23 Operation of this equipment shall be conducted in compliance with all data and specifications submitted with the application under which this permit is issued unless otherwise noted below.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-T24 This equipment shall be installed, operated and maintained in strict accord with those recommendations of the manufacturer/supplier and/or sound engineering principles which produce the minimum emissions of contaminants.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-T25 The operator shall maintain a log for this equipment, which, at a minimum, contains the information specified below. This log shall be maintained current and on-site for a minimum of two (2) years, and be provided to District, State and Federal personnel upon request:

- a. Monthly fuel use; and,
- b. Cumulative total fuel usage.

Verification: As part of the Monthly Compliance Report the project owner shall include information on operating hours of operation and fuel use to demonstrate compliance with this condition.

AQ-T26 This heater may be fired using liquefied petroleum gas (LPG), natural gas (NG) or liquefied natural gas (LNG).

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-T27 This heater shall only be used to liquefy and condition the heat transfer mixture during start up procedures associated with salt commissioning (excluding start-up of the heater).

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-T28 This heater shall be limited to the melting and conditioning of up to 35,000 tons of salt (excluding start-up of the heater).

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-T29 This equipment shall be removed from this facility within 60 days subsequent to power plant start up; the owner/operator shall within 60 days of power plant start up request that this permit be cancelled.

Verification: The project owner shall submit to the CPM as part of the last Monthly Compliance Report or within 30 days of equipment removal confirmation of the date of equipment removal in compliance with the requirements of this condition. The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-T30 Pursuant to District Rule 401, visible emissions associated with operation of this heater shall not exceed 20% opacity or Ringelmann 1.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

Temporary conditions AQ-T31 to AQ-T38 apply to the following equipment permit:

Permit No. C010830 (Wet Chemical Scrubber, Temporary; flow rate of approximately 3,000 acfm)

EQUIPMENT DESCRIPTION:

Temporary salt conditioning multi-stage chemical wet scrubbers with a 50 foot tall stack and a 1.13 foot diameter, operating with an exhaust temperature of 120 degrees F and a flow rate of 3,000 acfm.

AQ-T31 This equipment shall only be operated and maintained in strict accord with manufacturers and/or supplier's recommendations and/or sound engineering principles.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-T32 An operating air lock device shall be fitted in each material and/or liquid discharge port.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-T33 The overall water flow to this scrubbing system shall be kept at levels designed and recommended by system supplier.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-T34 The scrubbing system shall be equipped with a pressure gauge and water flow meter to allow for the measurements of the water flow and pressure to the venturi and impingement tray scrubbers.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-T35 The pressure drop across this scrubbing system shall be within the manufacturer's or design recommended range of **TBD** inches water column (WC) or greater.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-T36 The project owner shall maintain a log of all material throughput amounts so as to record the values referenced in the above condition. Additionally, a log shall be kept of all inspections, repairs, and maintenance on equipment. Such logs or records shall be maintained at the facility for two (2) years, and be provided to District, State and Federal personnel upon request.

Verification: As part of the Monthly Compliance Report the project owner shall include information on operating hours of operation demonstrate compliance with this condition.

AQ-T37 This equipment shall be operated concurrently with the salt blending and heating process associated with District Permits B010848, B010792, and B010801.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T38 Salt blending and salt conditioning operations are temporary and expected to be in service 24 hours per day, and up to 140 days during the salt commissioning phase. Subsequently, the salt milling and handling equipment, salt heaters and wet chemical scrubber shall be removed from the site within 60 days subsequent to the power plant start up; the owner/operator shall within 60 days of power plant start up request that this permit be cancelled.

Verification: The project owner shall submit to the CPM as part of the last Monthly Compliance Report or within 30 days of equipment removal confirmation of the date of equipment removal in compliance with the requirements of this condition. The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

Temporary conditions AQ-T39 to AQ-T43 apply to the following equipment permit:

Permit No. C010850 (Baghouse, Temporary)

EQUIPMENT DESCRIPTION:

Temporary Model **TBD**; airflow of **TBD** acfm at powered with a **TBD** hp motor, **TBD** Bags, **TBD** ft² of cloth area and Air-to-Cloth ratio of **TBD**.

AQ-T39 This equipment shall only be operated and maintained in strict accord with manufacturers and/or supplier's recommendations and/or sound engineering principles.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T40 The project owner shall maintain, on-site, an inventory of replacement bags sufficient to ensure compliance with applicable rules of District Regulation IV.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T41 This baghouse shall operate as part of the process known as the RSEP salt handling process, permitted by MDAQMD permit B010848.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-T42 Salt blending and commissioning operations are temporary and expected to be 24 hours per day, and up to 140 days during the salt system commissioning phase. Subsequently, the salt milling and handling equipment, including this baghouse, shall be removed from the site within 60 days subsequent to power plant start up; the owner/operator shall within 60 days of power plant start up request that this permit be cancelled.

Verification: The project owner shall submit to the CPM as part of the last Monthly Compliance Report or within 30 days of equipment removal confirmation of the date of

equipment removal in compliance with the requirements of this condition. The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-T43 The project owner shall maintain a log of all material throughput amounts so as to record the values referenced in the above condition. Additionally, a log shall be kept of all inspections, repairs, and maintenance on equipment. Such logs or records shall be maintained at the facility for two (2) years, and be provided to District, State and Federal personnel upon request.

Verification: As part of the Monthly Compliance Report the project owner shall include information on operating hours of operation demonstrate compliance with this condition.

Appendix AIR-1 - Greenhouse Gas Emissions

Testimony of William Walters, P.E.

SUMMARY OF CONCLUSIONS

The Rice Solar Project is a proposed addition to the state's electricity system. Rice Solar is a solar concentrating thermal power plant with thermal storage that uses heliostat mirrors to heat molten salt which is then used to generate steam that powers a steam turbine. The use of molten salt for thermal storage would allow this facility, unlike most thermal solar designs, to store heat and generate a limited amount of electricity (limit is based on size of "hot" storage tank) on demand at any time during the day or night. As a solar project, its greenhouse gas (GHG) emissions would be considerably less than the existing statewide average GHG emissions per unit of generation and considerably less than the GHG emissions from existing fossil fuel fired power plants providing generation to California, and thus would contribute to continued reduction of GHG emissions in the interconnected California and the western United States electricity systems.

While Rice Solar would emit some GHG emissions, the contribution to the system build-out of renewable resources to meet the goals of the Renewable Portfolio Standard (RPS) in California would result in a net cumulative reduction of energy generation and GHG emissions from new and existing fossil-fired electricity resources. Electricity is produced by operation of inter-connected generation resources. Operation of one power plant, like Rice Solar, affects all other power plants in the interconnected system. Rice Solar would be a must-take facility and its operation would affect the overall electricity system operation and GHG emissions in several ways:

- Rice Solar would provide low-GHG, renewable generation.
- Rice Solar's thermal storage design would provide dispatchable and flexible power that would ease its integration into the power distribution system and could help integrate the growing generation from intermittent renewable sources without power storage, such as wind and other types of solar generation.
- Rice Solar would facilitate to some degree the replacement of high GHG emitting (e.g., out-of-state coal) electricity generation that must be phased out to meet the State's 2006 Emissions Performance Standard.
- Rice Solar could facilitate to some extent the replacement of generation provided by aging fossil-fired power plants that use once-through cooling.

These system impacts would result in a net reduction in GHG emissions across the electricity system providing energy and capacity to California. Thus, staff concludes that the proposed project would result in a cumulative overall reduction in GHG emissions from power plants, does not worsen current conditions, and would not result in impacts that are cumulatively CEQA significant.

Staff concludes that the short-term minor emission of greenhouse gases during construction that are necessary to create this new, low GHG-emitting power generating facility would be sufficiently reduced by "best practices" and would be more than offset

by GHG emission reductions during operation. Thus, construction GHG emissions would not be CEQA significant.

The Rice Solar Project, as a renewable energy generation facility, is determined by rule to comply with the Greenhouse Gas Emission Performance Standard requirements of SB 1368 (Chapter 11, Greenhouse Gases Emission Performance Standard, Article 1, Section 2903 [b][1]).

The California Air Resources Board (ARB) has promulgated regulations for mandatory GHG emission reporting to comply with the California Global Warming Solutions Act of 2006 (AB 32 Núñez, Statutes of 2006, Chapter 488, Health and Safety Code sections 38500 et seq.) (ARB 2008a). The Rice Solar Project, which solely generates electricity from solar power, is exempt from the mandatory GHG emission reporting requirements for electricity generating facilities [CCR Title 17 §95101(c)(1)]. However, the proposed project may be subject to future reporting requirements and GHG reductions or trading requirements as additional state or federal GHG regulations are developed and implemented.

INTRODUCTION

Greenhouse gas (GHG) emissions are not criteria pollutants, but they are discussed in the context of cumulative impacts. However, on April 2, 2007, the U.S. Supreme Court found that GHGs are pollutants that must be covered by the federal Clean Air Act. In response, on September 30, 2009, the U.S. Environmental Protection Agency proposed to apply Prevention of Significant Deterioration (PSD) requirements to facilities whose carbon dioxide-equivalent emissions exceed 25,000 tons per year (U.S.EPA 2009c). The rule making is not finalized, but the GHG emissions for Rice Solar are not expected to exceed this amount.

The federal and state governments have demonstrated a clear willingness to address global climate change through research, adaptation and inventory reductions. In that context, the agencies evaluate the GHG emissions from the proposed project, present information on GHG emissions related to electricity generation, and describe the applicable GHG standards and requirements. This analysis has been prepared by staff and serves as staff's testimony in the Energy Commission's RSEP licensing proceeding in accordance with CEQA. This analysis also serves as BLM's and Western's assessment of the proposed RSEP in accordance with NEPA. The analysis evaluates greenhouse gas impacts associated with the proposed RSEP's construction, operating and decommissioning activities.

Generation of electricity can produce greenhouse gases with the criteria air pollutants that have been traditionally regulated under the federal and state Clean Air Acts. For fossil fuel-fired power plants, the GHG emissions include primarily carbon dioxide, with much smaller amounts of nitrous oxide (N₂O, not NO or NO₂, which are commonly known as NO_x or oxides of nitrogen), and methane (CH₄ – often from unburned natural gas). For solar energy generation projects the stationary source GHG emissions are much smaller than fossil fuel-fired power plants, but the associated maintenance vehicle emissions are higher. Other sources of GHG emissions include sulfur hexafluoride (SF₆) from high voltage equipment and hydrofluorocarbons (HFCs) and perfluorocarbons

(PFCs) from refrigeration/chiller equipment. GHG emissions from the electricity sector are dominated by CO₂ emissions from carbon-based fuels; other sources of GHG emissions are small and also are more likely to be easily controlled or reused or recycled, but are nevertheless documented here as some of the compounds have very high global warming potentials.

Global warming potential is a relative measure, compared to carbon dioxide, of a compound's residence time in the atmosphere and ability to warm the planet. Mass emissions of GHGs are converted into carbon dioxide equivalent (CO₂E) metric tonnes (MT) for ease of comparison.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

The following federal, state, and local laws and policies in **Greenhouse Gas Table 1** pertain to the control and mitigation of greenhouse gas emissions. Staff's analysis examines the proposed project's compliance with these requirements.

GLOBAL CLIMATE CHANGE AND ELECTRICITY PRODUCTION

There is general scientific consensus that climate change is occurring and that human activity contributes in some measure (perhaps substantially) to that change. Man-made emissions of greenhouse gases, if not sufficiently curtailed, are likely to contribute further to continued increases in global temperatures. Indeed, the California Legislature finds that "[g]lobal warming poses a serious threat to the economic well-being, public health, natural resources, and the environment of California" (Cal. Health & Safety Code, sec. 38500, division 25.5, part 1).

Greenhouse Gas Table 1
Laws, Ordinances, Regulations, and Standards (LORS)

Applicable Law	Description
Federal	
40 Code of Federal Regulations (CFR) Part 98	This rule requires mandatory reporting of GHG emissions for facilities that emit more than 25,000 metric tons of CO ₂ equivalent emissions per year.
State	
California Global Warming Solutions Act of 2006, AB 32 (Stats. 2006; Chapter 488; Health and Safety Code sections 38500 et seq.)	This act requires the California Air Resources Board (ARB) to enact standards that will reduce GHG emission to 1990 levels by 2020. Electricity production facilities will be regulated by the ARB.
California Code of Regulations, tit. 17, Subchapter 10, Article 2, sections 95100 et. seq.	These ARB regulations implement mandatory GHG emissions reporting as part of the California Global Warming Solutions Act of 2006 (Stats. 2006; Chapter 488; Health and Safety Code sections 38500 et seq.)
Title 20, California Code of Regulations, section 2900 et seq.; CPUC Decision D0701039 in proceeding R0604009	The regulations prohibit utilities from entering into long-term contracts with any base load facility that does not meet a greenhouse gas emission standard of 0.5 metric tonnes carbon dioxide per megawatt-hour (0.5 MTCO ₂ /MWh) or 1,100 pounds carbon dioxide per megawatt-hour (1,100 lbs CO ₂ /MWh).

In 1998, the Energy Commission identified a range of strategies to prepare for an uncertain climate future, including a need to account for the environmental impacts associated with energy production, planning, and procurement (CEC 1998, p.5). In 2003, the Energy Commission recommended that the state require reporting of greenhouse gases (GHG) or global climate change¹⁰ emissions as a condition of state licensing of new electric generating facilities (CEC 2003, IEPR p. 42). In 2006, California enacted the California Global Warming Solutions Act of 2006 (AB 32). It requires the California Air Resources Board (ARB) to adopt standards that will reduce statewide GHG emissions to statewide GHG emissions levels in 1990, with such reductions to be achieved by 2020.¹¹ To achieve this, ARB has a mandate to define the 1990 emissions level and achieve the maximum technologically feasible and cost-effective GHG emission reductions.

The ARB adopted early action GHG reduction measures in October 2007, adopted mandatory reporting requirements and the 2020 statewide target in December 2007, and adopted a statewide scoping plan in December 2008 to identify how emission reductions will be achieved from major sources of GHG via regulations, market mechanisms, and other actions. ARB staff is developing regulatory language to implement its plan and holds ongoing public workshops on key elements of the recommended GHG reduction measures, including market mechanisms (ARB 2006). The regulations must be effective by January 1, 2011 and mandatory compliance commences on January 1, 2012. The mandatory reporting requirements are effective for electric generating facilities with a nameplate capacity equal or greater than one megawatt (MW) capacity if their emissions exceed 2,500 metric tonnes per year. The due date for initial reports by existing facilities was June 1, 2009.

Examples of strategies that the state might pursue for managing GHG emissions in California, in addition to those recommended by the Energy Commission and the Public Utilities Commission, were identified in the California Climate Action Team's Report to the Governor (CalEPA 2006). The scoping plan approved by ARB in December 2008 builds upon the overall climate policies of the Climate Action Team report and shows the recommended strategies to achieve the goals for 2020 and beyond. Some strategies focus on reducing consumption of petroleum across all areas of the California economy. Improvements in transportation energy efficiency (fuel economy), land use planning, and alternatives to petroleum-based fuels are slated to provide substantial reductions by 2020 (CalEPA 2006). The scoping plan includes a requirement for 33% of California's electrical energy to be provided from renewable sources by 2020 (implementing California's 33% RPS goal), aggressive energy efficiency targets, and a cap-and-trade system that includes the electricity sector (ARB 2008b).

It is likely that GHG reductions mandated by ARB will not be uniform across emitting sectors, in that reductions will be based on cost-effectiveness (i.e., the greatest effect for the least cost). For example, the ARB proposes a 40% reduction in GHG from the

¹⁰ Global climate change is the result of greenhouse gases, or air emissions with global warming potentials, affecting the global energy balance, and thereby, climate of the planet. The term greenhouse gases (GHG) and global climate change (GCC) gases are used interchangeably.

¹¹ Governor Schwarzenegger has also issued Executive Order S-3-05 establishing a goal of 80% below 1990 levels by 2050.

electricity sector, even though that sector currently only produces about 25% of the state's GHG emissions. In response, in September 2008 the Energy Commission and the Public Utilities Commission provided recommendations (CPUC 2008) to ARB on how to achieve such reductions through both programmatic and regulatory approaches, and identified points of regulation should ARB decide that a multi-sector cap and trade system is warranted.

The Energy Commission's *2007 Integrated Energy Policy Report* (IEPR) also addressed climate change within the electricity, natural gas, and transportation sectors (CEC 2007). For the electricity sector, it recommended such approaches as pursuing all cost-effective energy efficiency measures and meeting the Governor's stated goal of a 33% renewable portfolio standard. The Energy Commission's *2009 Integrated Energy Policy Report* continues to emphasize the importance of meeting greenhouse gas emissions reduction goals along with other important statewide issues such as reducing the use of once-through cooling in coastal California power plants (CEC 2009d).

SB 1368¹², enacted in 2006, and regulations adopted by the Energy Commission and a Public Utilities Commission decision ((D. 07-01-039; January 25, 2007) pursuant to the bill, prohibits California utilities from entering into long-term commitments with any base load facilities that exceed the Emission Performance Standard of 0.500 metric tonnes CO₂ per megawatt-hour¹³ (1,100 pounds CO₂/MWh). Specifically, the SB 1368 Emission Performance Standard (EPS) applies to power from new power plants, new investments in existing power plants, and new or renewed contracts with terms of five years or more, including contracts with power plants located outside of California.¹⁴ If a project that is designed or intends to provide base load energy (instate or out of state) plans to sell electricity to a California utility, that utility will have to demonstrate that the project meets the EPS. *Base load* units are defined as units that operate at a capacity factor higher than 60%. As a renewable electricity generating facility, Rice Solar is determined by rule to be compliant with the SB 1368 EPS.

In addition to these programs, California is involved in the Western Climate Initiative, a multi-state and international effort to establish a cap and trade market to reduce greenhouse gas emissions in the Western United States and the Western Electricity Coordinating Council (WECC). The timelines for the implementation of this program are similar to those of AB 32, with full roll-out beginning in 2012. And as with AB 32, the electricity sector has been a major focus of attention.

ELECTRICITY PROJECT GREENHOUSE GAS EMISSIONS

Electricity use can be as simple as turning on a switch to operate a light or fan. The system to deliver adequate and reliable electricity supply is complex and variable. But it operates as an integrated whole to meet demand, such that the dispatch of a new source of generation generally curtails or displaces one or more less efficient or less competitive existing sources. Within the system, generation resources provide

¹² Public Utilities Code § 8340 et seq.

¹³ The Emission Performance Standard only applies to carbon dioxide, and does not include emissions of other greenhouse gases converted to carbon dioxide equivalent.

¹⁴ See Rule at http://www.cpuc.ca.gov/PUBLISHED/FINAL_DECISION/64072.htm

electricity, or energy, generating capacity, and ancillary services to stabilize the system and facilitate electricity delivery, or movement, over the grid. *Capacity* is the instantaneous output of a resource, in megawatts. It is also the potential output of a resource; hence Rice Solar has a capacity of 150 MW. *Energy* is the capacity output over a unit of time, for example an hour or year, generally reported as megawatt-hours or gigawatt-hours (GWh). Ancillary services¹⁵ include regulation, spinning reserve, non-spinning reserve, voltage support, and black start capability. Individual generation resources can be built and operated to provide only one specific service. Alternatively, a resource may be able to provide one or all of these services, depending on its design and constantly changing system needs and operation.

California is actively pursuing policies to reduce GHG emissions that include adding non-GHG emitting renewable generation resources to the system mix. The generation of electricity using fossil fuels, even in a back-up generator at a thermal solar plant, produces air emissions known as greenhouse gases in addition to the criteria air pollutants that have been traditionally regulated under the federal and state Clean Air Acts. Greenhouse gas emissions contribute to the warming of the earth's atmosphere, leading to climate change.

PROJECT CONSTRUCTION

Construction of industrial facilities such as power plants requires coordination of numerous equipment and personnel. The concentrated on-site activities result in short-term, unavoidable increases in vehicle and equipment emissions that include greenhouse gases. Additionally, for this facility there are GHG emissions from the salt conditioning process that are a one-time GHG emission source prior to commercial operation. The greenhouse gas emissions estimate, determined for the entire construction and salt conditioning period one-time emission sources, are presented below in **Greenhouse Gas Table 2**.

Greenhouse Gas Table 2
Estimated Rice Solar Construction/Commissioning Greenhouse Gas Emissions

Construction Element	CO2-Equivalent (MTCO2E) ^{a,b}
On-Site Construction Equipment	6,333
On-Site Motor Vehicles	104
Off-Site Motor Vehicles	9,116
Transmission Line Construction Equipment	599
Construction Subtotal	16,152
Salt Conditioning Element	
Salt Melting	9,489
Temporary Salt Heater	1,374
Temporary Electrical Heating Indirect Emissions	1,595
Conditioning Subtotal	12,458
Construction and Salt Conditioning Total	28,610

^a One metric tonne (MT) equals 1.1 short tons or 2,204.6 pounds or 1,000 kilograms

^b The vast majority of the CO2E emissions, over 99%, are CO₂ from these combustion sources.

¹⁵ See CEC 2009b, page 95.

PROJECT OPERATIONS

Operations GHG emissions are shown in **Greenhouse Gas Table 3**. Operation of the proposed Rice Solar Project would cause GHG emissions from the facility maintenance fleet and employee trips, two emergency generator engines, two fire water pump engines, and sulfur hexafluoride leaks, hydrofluorocarbons leaks, and perfluorocarbons leaks from new electrical component and other equipment. These emissions include the ongoing operating emission sources that would be active during the initial commissioning phase.

Greenhouse Gas Table 3
Estimated Rice Solar Operating Greenhouse Gas Emissions

Equipment Leakage (HFC -134a)	4
Equipment Leakage (PFC-14)	3
Total Project GHG Emissions – MTCO₂E^b	994
Facility Net MWh per year ^c	450,000
Facility GHG Performance (MTCO ₂ E/MWh)	0.0022

Sources: SR 2009a; CH2MHill 2010a; CH2M-Hill 2010e; and CH2M-Hill 2010l

^a One metric tonne (MT) equals 1.1 short tons or 2,204.6 pounds or 1,000 kilograms.

^b The vast majority of the CO₂E emissions, over 99%, are CO₂ from these emission sources.

^c This represents net MWh including the reduction in total net generation from direct parasitic load and the use of grid power, where the net GHG emissions for grid power use is also assumed to be netted out by the reduction in gross facility MWh generation needed to cover the grid power use.

Greenhouse Gas Table 3 shows what the proposed project, as permitted, could potentially emit in greenhouse gases on an annual basis. All emissions are converted to CO₂-equivalent and totaled. Electricity generation GHG emissions are generally dominated by CO₂ emissions from the carbon-based fuels; other sources of GHG are typically small and also are more likely to be easily controlled or reused/recycled. For this solar project the primary fuel, solar energy, is greenhouse gas free, but there is direct and indirect gasoline and diesel fuel use in the maintenance vehicles, offsite delivery vehicles, staff and employee vehicles, and the two emergency generator engines and two emergency fire pump engines. Another GHG emission source for the proposed project is the leakage of SF₆ from electrical equipment and the leakage of HFCs and PFCs from refrigeration and fire suppression equipment leakage, respectively.

The proposed project is estimated to emit, directly from primary and secondary emission sources on an annual basis, nearly 1,000 metric tonnes of CO₂-equivalent GHG emissions per year. The Rice Solar Project, as a renewable energy generation facility, is determined by rule to comply with the Greenhouse Gas Emission Performance Standard requirements of SB 1368 (Chapter 11, Greenhouse Gases Emission Performance Standard, Article 1, Section 2903 [b][1]). Regardless, Rice Solar

has an estimated GHG emission rate of 0.0022 MTCO₂E/MWh, well below the Greenhouse Gas Emission Performance Standard of 0.500 MTCO₂/MWh.

Solar Project Energy Payback Time

The beneficial energy and greenhouse gas impacts of renewable energy projects can also be measured by the *energy payback time*¹⁶. **Greenhouse Gas Tables 2 and 3** provide an estimate of the onsite construction and operation emissions, employee transportation emissions, and the final segment of offsite materials and consumables transportation. However, there are additional direct transportation and indirect manufacturing GHG emissions associated with the construction and operation of the proposed project, which are all considered in the determination of the energy payback time. A document sponsored by Greenpeace estimates that the energy payback time for concentrating solar power plants, such as Rice Solar, to be on the order of 5 months (Greenpeace 2005, Page 9); and the project life for Rice Solar is estimated to be 30 years (SR 2009a, p. 2-51). Therefore, the proposed project's GHG emissions reduction potential from energy displacement would be substantial¹⁷.

Natural Carbon Uptake Reduction

This proposed project would cause the clearing of land and removal of vegetation, which would reduce the ongoing natural carbon uptake by vegetation. A study of the Mojave Desert indicated that the desert may uptake carbon in amounts as high as 100 grams per square meter per year (Wohlfahrt et. al. 2008). This would equate to a maximum reduction in carbon uptake, calculated as CO₂, of 1.48 MT of CO₂ per acre per year for areas with complete vegetation removal. For this 1,410 acre proposed project the maximum equivalent loss in carbon uptake assuming complete vegetation removal would be 2,087 MT of CO₂ per year, which would correspond to 0.005 MT of CO₂ per MWh generated. Therefore, the natural carbon uptake loss is negligible in comparison with the reduction in fossil fuel CO₂ emissions, which can range from 0.35 to 1.0 MT of CO₂ per MWh depending on the fuel and technology, that is enabled by this proposed project.

CLOSURE AND DECOMMISSIONING

Closure and decommissioning, as a one-time limited duration event, would have emissions that are similar in type and magnitude, but likely lower than, the construction emissions as discussed above.

¹⁶ The energy payback time is the time required to produce an amount of energy as great as what was consumed during production, which in the context of a solar power plant includes all of the energy required during construction and operation.

¹⁷ The GHG displacement for the project would be similar to, but not exactly the same as, the amount of energy produced after energy payback is achieved multiplied by the average GHG emissions per unit of energy displaced. The average GHG emissions for the displaced energy over the project life is not known but currently fossil fuel fired power plants have GHG emissions that range from 0.35 MT/MWh CO₂E for the most efficient combined cycle gas turbine power plants to over 1.0 MT/MWh for coal fired power plants.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

Staff assesses four kinds of impacts: construction, operation, closure and decommissioning, and cumulative effects. As the name implies, construction impacts result from the emissions occurring during the construction of the proposed project. The operation impacts result from the emissions of the proposed project during operation. Cumulative impacts analysis assesses the impacts that result from the proposed project's incremental effect viewed over time. The impact of GHG emissions caused by this solar facility is characterized by considering how the power plant would affect the overall electricity system. The integrated electricity system depends on non-fossil and fossil-fueled generation resources to provide energy and satisfy local capacity needs. As directed by the Energy Commission's adopted order initiating an informational (OII) proceeding (08-GHG OII-1) (CEC 2009a), staff is refining and implementing the concept of a "blueprint" that describes the long-term roles (i.e., retirements and displacement) of fossil-fueled power plants in California's electricity system as we move to a high-renewable, low-GHG electricity system, which would include projects like Rice Solar.

PROPOSED PROJECT

Construction/Salt System Commissioning Impacts

Staff concludes that the GHG emission increases from the construction and one-time salt system commissioning activities would not be CEQA significant for several reasons. First, the period of construction would be short-term and the emissions intermittent during that period, not ongoing during the life of the proposed project. Second, best practices control measures that staff recommends, such as limiting idling times and requiring, as appropriate, equipment that meet the latest emissions standards, would further minimize greenhouse gas emissions since the use of newer equipment would increase efficiency and reduce GHG emissions and be compatible with low-carbon fuel (e.g., bio-diesel and ethanol) mandates that will likely be part of the ARB regulations to reduce GHG from construction vehicles and equipment. And lastly, these temporary GHG emissions are necessary to create this renewable energy source that would provide power with a very low GHG emissions profile, and the construction emissions would be more than offset by the reduction in fossil fuel fired generation that would be enabled by this proposed project. If the proposed project construction and one-time salt conditioning GHG emissions were distributed over the 30 year life of the proposed project they would only increase the project life time annual facility GHG emissions rate by 0.0021 MT CO₂-eq per MW.

Direct/Indirect Operation Impacts and Mitigation

The proposed Rice Solar project promotes the state's efforts to move towards a high-renewable, low-GHG electricity system, and, therefore, reduces both the amount of natural gas used by electricity generation and greenhouse gas emissions.

Net GHG emissions for the integrated electric system will decline when new renewable power plants are added to: 1) move renewable generation towards the 33% target; 2) improve the overall efficiency, or GHG emission rate, of the electric system; or 3) serve load growth or capacity needs more efficiently, or with fewer GHG emissions.

The Role of Rice Solar in Renewables Goals/Load Growth

As California moves towards an increased reliance on renewable energy by implementing the Renewables Portfolio Standard (RPS), non-renewable energy resources will be displaced. These reductions in non-renewable energy, shown in **Greenhouse Gas Table 4**, could be as much as 36,500 GWh. These assumptions are conservative in that the forecasted growth in electricity retail sales assumes that the impacts of planned increases in expenditures on (uncommitted) energy efficiency are already embodied in the current retail sales forecast¹⁸. Energy Commission staff estimates that as much as 18,000 GWh of additional savings due to uncommitted energy efficiency programs may be forthcoming.¹⁹ This would reduce non-renewable energy needs by a further 12,000 GWh given a 33% RPS.

Greenhouse Gas Table 4
Estimated Changes in Non-Renewable Energy Potentially Needed to Meet California Loads, 2008-2020

California Electricity Supply	Annual GWh	
Statewide Retail Sales, 2008, estimated ^a	264,794	
Statewide Retail Sales, 2020, forecast ^a	289,697

The Role of Rice Solar in Retirements/Replacements

Rice Solar would be capable of annually providing 450 GWh of renewable generation energy to replace resources that are or will likely be precluded from serving California loads. State policies, including GHG goals, are discouraging or prohibiting new contracts and new investments in high GHG-emitting resources such as coal-fired generation, generation that relies on water for once-through cooling, and aging power

¹⁸ Energy efficiency savings are already represented in the current Energy Commission demand forecast adopted December 2009 (CEC 2009c).

¹⁹ See *Incremental Impacts of Energy Efficiency Policy Initiatives Relative to the 2009 Integrated Energy Policy Report Adopted Demand Forecast* (CEC-200-2010-001-D, January, 2010), page 2. Table 1 indicates that additional conservation for the three investor-owned utilities may be as high as 14,374 GWh. Increasing this value by 25% to account for the state's publicly-owned utilities yields a total reduction of 17,967 GWh.

plants (CEC 2007). Some of the existing plants that are likely to require substantial capital investments to continue operation in light of these policies may be unlikely to undertake the investments and will retire or be replaced.

Replacement of High GHG-Emitting Generation

High GHG-emitting resources, such as coal, are effectively prohibited from entering into new long-term contracts for California electricity deliveries as a result of the Emissions Performance Standard adopted in 2007 pursuant to SB 1368. Between now and 2020, more than 18,000 GWh of energy procured by California utilities under these contracts will have to reduce GHG emissions or be replaced; these contracts are presented in **Greenhouse Gas Table 5**.

This represents almost half of the energy associated with California utility contracts with coal-fired resources that will expire by 2030. If the State enacts a carbon adder²⁰, all the coal contracts (including those in **Greenhouse Gas Table 5**, which expire by 2020 and, other contracts that expire beyond 2020 and are not shown in the table) may be divested at an accelerated rate as coal-fired energy becomes uncompetitive due to the carbon adder or the capital needed to capture and sequester the carbon emissions. Also shown are the approximate 500 MW of in-state coal and petroleum coke-fired capacity that may be unlikely to contract with California utilities for baseload energy due to the SB1368 Emission Performance Standard. As these contracts expire, new and existing generation resources will replace the lost energy and capacity. Some will come

²⁰ A carbon adder or carbon tax is a specific value added to the cost of a project for per ton of associated carbon or carbon dioxide emissions. Because it is based on, but not limited to, actual operations and emission and can be trued up at year end, it is considered a simple mechanism to assign environmental costs to a project.

from renewable generation such as the proposed project; some will come from new and existing natural gas fired generation. All of these new facilities will have substantially lower GHG emissions rates than coal and petroleum coke-fired facilities, which typically averages about 1.0 MTCO₂/MWh without carbon capture and sequestration. Thus, new renewable facilities will result in a net reduction in GHG emissions from the California electricity sector.

Retirement of Generation Using Once-Through Cooling

The State Water Resource Control Board (SWRCB) has proposed significant restrictions on the operation of once-through cooling (OTC) units, shown in **Greenhouse Gas Table 6**, which will likely require extensive capital to retrofit, or retirement, or substantial curtailment of dozens of generating units. In 2008, these units collectively produced almost 58,000 GWh. While the more recently built OTC facilities may well install dry or wet cooling towers and continue to operate, the aging OTC plants are not likely to be retrofit to use dry or wet cooling towers without the power generation also being retrofit or replaced to use a more efficient and lower GHG emitting combined cycle gas turbine technology. Most of these existing OTC units operate at low capacity factors, suggesting a limited ability to compete in the current electricity market and reliance on capacity contracts offered to these OTC facilities since they are needed for reliability. Although the timing would be uncertain, new resources are expected to be more competitive than aging plants and would displace the energy provided by OTC facilities and likely facilitate if not accelerate their retirements.

Any additional costs associated with complying with the SWRCB regulation would be amortized over a limited revenue stream today and into the foreseeable future. Their energy and much of their dispatchable, load-following capability will have to be replaced. These units constitute over 15,000 MW of merchant capacity and 17,800 GWh of merchant energy. Of this, much but not all of the capacity and energy are in local reliability areas, requiring a large share of replacement capacity – absent transmission upgrades – to locations in the same local reliability area. **Greenhouse Gas Table 6** provides a summary of the utility and merchant energy supplies affected by the OTC regulations.

New renewable generation resources will emit substantially less GHG emissions on average than other energy generation sources. Existing aging and OTC natural gas facility generation typically averages 0.6 to 0.7 MTCO₂/MWh, which is much less efficient, higher GHG emitting than a renewable energy project like Rice Solar. A project like Rice Solar, located far from the coastal load pockets like the Los Angeles Local Reliability Area (LRA), would more likely provide energy support to facilitate the retirement of some aging and/or OTC power plants, but would not likely provide any local capacity support at or near the coastal OTC units. Regardless, due to its being both dispatchable and having very low greenhouse gas emissions, Rice Solar would serve to reduce GHG emissions from the electricity sector.

- a. OTC Humboldt Bay Units 1 and 2 are included in this list. They must retire in 2010 when the new Humboldt Bay Generating Station (not ocean-cooled), currently under construction, enters commercial operation.
- b. Units are aging but are not OTC.

Closure and Decommissioning

Eventually the facility would close, either at the end of its useful life or due to some unexpected situation such as a natural disaster or catastrophic facility breakdown. When the facility closes, all sources of air emissions would cease to operate and thus impacts associated with those greenhouse gas emissions would no longer occur. The only other expected, albeit temporary, GHG emissions would be equipment exhaust (off-road and on-road) from dismantling activities. These activities would be of much a shorter duration than construction of the proposed project, equipment used to dismantle

the facility are assumed to have lower comparative GHG emissions due to technology advancement, and would be required to be controlled in a manner at least equivalent to that required during construction. It is assumed that the beneficial GHG impacts of this facility, displacement of fossil fuel fired generation, would be replaced by the construction of newer more efficiency renewable energy or other low GHG generating technology facilities. Also, the recycling of the facility components (steel, concrete, etc.) could indirectly reduce GHG emissions from decommissioning activities. Therefore, while there would be temporary adverse greenhouse gas CEQA impacts during decommissioning they are determined to be less than significant.

REDUCED ACREAGE ALTERNATIVE

The Reduced Acreage Alternative would be an approximately 148 MW project, with a 7.2% smaller heliostat field. It would be located in the same 2,560-acre square-shaped parcel within the larger 3,324-acre ownership property as the proposed project. However, the heliostat field would occupy about 1,270 acres instead of the 1,370 acres required for the proposed project. The receiver location would remain the same, with the edges of the field contracting towards the center. The heliostat footprint of the Reduced Acreage Alternative is shown in **Alternatives Figure 1**. The site layout (e.g. administration/shop building and evaporation ponds); 653-foot total height of the solar tower and receiver; and transmission interconnection to WAPA's Parker-Blythe transmission line would be the same as the proposed project.

The Reduced Acreage Alternative is evaluated in this SA/DEIS because it would eliminate about 100 acres of the proposed project footprint, reducing impacts to ephemeral washes, the loss of land considered habitat for the state and federally listed threatened desert tortoise and impacts to the historic Rice airfield. The Reduced Acreage Alternative would allow the applicant to contribute clean, renewable energy to help meet the State's energy goals, while minimizing impacts to the desert environment. A limited acreage alternative was suggested in scoping comments.

The results of the Reduced Acreage Alternative would be the following:

- The impacts of the proposed project would not occur on the lands not used due to the smaller project size. However, the land on which the project is proposed would become available to other uses, including another solar project.
- The benefits of the proposed project in displacing fossil fuel fired generation and reducing associated greenhouse gas emissions from gas-fired generation would be minimally reduced due to the 1.3% drop in generating capacity. Both State and Federal law support the increased use of renewable power generation.

If the Reduced Acreage Alternative were approved, other renewable projects would likely be developed that would compensate for the small loss of generation compared to the proposed project on other sites in Riverside County, the Mojave Desert, or in adjacent states as developers strive to provide renewable power that complies with utility requirements and State/Federal mandates. For example, there are several pending solar and wind projects in the I-10 corridor that would be located south of the Rice Solar project site, and there are dozens of other wind and solar projects that have applications pending with the Bureau of Land Management (BLM) in the California Desert District.

NORTH OF DESERT CENTER ALTERNATIVE

The North of Desert Center Alternative would be a 150 MW solar thermal facility located on approximately 2,643 acres of land. It is located along Desert Center Rice Road (State Route 177) east of Kaiser Road, north of Oasis Road, and approximately 1.6 miles north of I-10. The North of Desert Center Alternative is primarily private land with smaller sections of BLM land in the eastern portion of the site. It is largely fallow agricultural land. The existing SCE 161-kV transmission line (from the Blythe-2 substation to the Eagle Mountain-1 substation) that traverses the alternative site would be realigned to roughly follow the site boundary. A new 0.125-mile transmission line (along Osborne Ave.) and substation would interconnect to the realigned SCE line at the northeast boundary of the site. The boundaries and transmission realignment of the North of Desert Center Alternative are illustrated in **Alternatives Figure 2**.

The North of Desert Center Alternative is evaluated in this SA/DEIS because it would reduce impacts to cultural resources; the RSEP is located on the historic Rice Army Airfield. The North of Desert Center Alternative would allow the applicant to contribute clean, renewable energy to help meet the State's energy goals, while minimizing impacts to the desert environment.

The results of the North of Desert Center Alternative would be the following:

- There could be a very small increase or decrease in the loss of natural carbon uptake depending on the total amount of disturbed acres and carbon update quality of those acres used for this alternative in comparison with those of the proposed project.
- The benefits of the proposed project in displacing fossil fuel fired generation and reducing associated greenhouse gas emissions from gas-fired generation would not be impacted by this alternative assuming that this alternative would use the same molten salt thermal storage technology.

SR 62/RICE VALLEY ROAD TRANSMISSION LINE ALTERNATIVE

The SR 62/Rice Valley Road Transmission Line Alternative would interconnect to Western Area Power Administration's (Western) 161-kV/230-kV Parker-Blythe transmission line at the same location as the proposed project transmission line. This alternative transmission line would exit the power block directly to the east and follow a proposed access road within the heliostat field. The tie-in would then turn north inside the RSEP property boundary and run along the RSEP's circular perimeter road to the north and northwest. At the north end of the heliostat field, the route would traverse the construction laydown area on previously disturbed land over a distance of approximately 500 feet to the southern side of State Route 62. The route would follow State Route 62 approximately 3.8 miles east to the junction of Rice Valley Road. It would then trend south to follow the unpaved Rice Valley Road for 4.1 miles to its juncture with the applicant's proposed new transmission line alignment and continue southeast for 5.4 miles along the proposed alignment to Western's Parker-Blythe transmission line. The SR 62/Rice Valley Road Transmission Line Alternative route is illustrated in **Alternatives Figure 3**.

The SR 62/Rice Valley Road Transmission Line Alternative is evaluated in this SA/DEIS because it would avoid the permanent loss of 13.4 acres of foraging and cover habitat for plant and animal species, including the state and federally listed threatened desert tortoise, and it would avoid the creation of a new 4.6 mile vehicle access route between the proposed solar facility and the proposed junction of the new transmission line access road with the existing Rice Valley road. The proposed new vehicle access route would necessitate additional enforcement and maintenance to prevent unauthorized off-road vehicle access, propagation of new, unauthorized vehicle routes, and consequent habitat damage, soil erosion, and vehicle disturbance.

The results of the SR 62/Rice Valley Road Transmission Line Alternative would be the following:

- The impacts of the proposed project would not occur on the lands not used due to the revised transmission route, including a small lessening in the loss of natural carbon uptake that would otherwise occur from the lands proposed to be disturbed for the proposed project's transmission route.
- The benefits of the proposed project in displacing fossil fuel fired generation and reducing associated greenhouse gas emissions from gas-fired generation would not be impacted by this alternative.

NO PROJECT/NO ACTION ALTERNATIVE

No Project and No Action on Rice Solar Energy Project transmission line application and interconnection request. No CDCA land use plan amendment.

Under this alternative, the proposed Rice Solar Energy Project would not be approved by the Energy Commission; BLM would not approve the transmission line application and would not amend the CDCA Plan; and Western would not approve the interconnection request. As a result, no solar energy project would be constructed on the project site, BLM would continue to manage the land encompassing the transmission line consistent with the existing land use designation in the CDCA Land Use Plan of 1980, as amended, and Western would continue to operate the Parker Blythe Transmission Line under current conditions.

Because there would be no amendment to the CDCA Plan and no solar project approved for the site under this alternative, it is expected that the site would continue to remain in its existing condition, with no new structures or facilities constructed or operated on the site. The results of this alternative would be the following:

- The impacts of the proposed project would not occur. However, the land on which the project is proposed would become available to other uses, including another renewable energy project.
- The benefits of the proposed project in displacing fossil fuel fired generation and reducing associated greenhouse gas emissions from gas-fired generation would not occur. Both State and Federal law support the increased use of renewable power generation.

If the proposed project is not approved, renewable energy projects would likely be developed on other sites in Riverside County, the Mojave Desert, or in adjacent states as developers strive to provide renewable power that complies with utility requirements and State/Federal mandates.

CUMULATIVE IMPACTS

Cumulative impacts are defined as “two or more individual effects which, when considered together, are considerable or . . . compound or increase other environmental impacts” (CEQA Guidelines § 15355). “A cumulative impact consists of an impact that is created as a result of a combination of the project evaluated in the EIR together with other projects causing related impacts” (CEQA Guidelines § 15130[a][1]). Such impacts may be relatively minor and incremental, yet still be significant because of the existing environmental background, particularly when one considers other closely related past, present, and reasonably foreseeable future projects. This definition is consistent with NEPA cumulative impact assessment requirements/guidance.

This entire GHG assessment is a cumulative impact assessment and the findings described elsewhere in this section are cumulative impact findings. The proposed project alone would not be sufficient to change global climate, but would emit greenhouse gases and therefore has been analyzed as a potential cumulative impact in the context of existing GHG regulatory requirements and GHG energy policies.

COMPLIANCE WITH LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

Rice Solar, as a solar energy generation project, is exempt from the mandatory GHG emission reporting requirements for electricity generating facilities as currently required by the California Air Resources Board (ARB) for compliance with the California Global Warming Solutions Act of 2006 (AB 32 Núñez, Statutes of 2006, Chapter 488, Health and Safety Code sections 38500 et seq.) (ARB 2008a).

The Rice Solar Project, as a renewable energy generation facility, is determined by rule to comply with the Greenhouse Gas Emission Performance Standard requirements of SB 1368 (Chapter 11, Greenhouse Gases Emission Performance Standard, Article 1, Section 2903 [b][1]).

Since the proposed project would have emissions that are below 25,000 MT/year of CO₂E, the proposed project would not be subject to federal mandatory reporting of greenhouse gases. It would also be exempt from the state’s greenhouse gas reporting requirements.

NOTEWORTHY PUBLIC BENEFITS

Greenhouse gas related noteworthy public benefits include the construction of renewable and low-GHG emitting generation technologies and the potential for successful integration into the California and greater WECC electricity systems. Additionally, the Rice Solar project would contribute to meeting the state’s AB 32 goals.

CONCLUSIONS

The Rice Solar Project would emit considerably less greenhouse gases (GHG) than existing power plants and most other generation technologies, and thus would contribute to continued improvement of the overall western United States, and specifically California, electricity system GHG emission rate average. The proposed project would lead to a net reduction in GHG emissions across the electricity system that provides energy and capacity to California. Additionally, the proposed project's thermal storage allows for a limited amount of dispatchable power generation, which would allow power generation at the most desired times of the day that would increase the GHG emission reduction potential over other non-dispatchable renewable energy projects, and which would also help integrate non-dispatchable renewable power into the power distribution system. Thus, staff concludes that the proposed project's operation would result in a cumulative overall reduction in GHG emissions from the state's power plants that would create a beneficial effect, would not worsen current conditions, and would thus not result in CEQA impacts that are cumulatively significant.

Staff concludes that the GHG emission increases typical from construction and decommissioning activities would not be CEQA significant for several reasons. First, the periods of construction and decommissioning would be short-term and not ongoing during the life of the proposed project. Second, the best practices control measures that staff recommends, such as limiting idling times and requiring, as appropriate, equipment that meets the latest emissions standards, would further minimize greenhouse gas emissions since the use of newer equipment would increase efficiency and reduce GHG emissions and be compatible with low-carbon fuel (e.g., bio-diesel and ethanol) mandates that will likely be part of the ARB regulations to reduce GHG from construction vehicles and equipment. Finally, the construction and decommissioning emissions are miniscule when compared to the reduction in fossil-fuel power plant greenhouse gas emissions during project operation. For all these reasons, staff would conclude that the short-term emission of greenhouse gases during construction would be sufficiently reduced and would be offset during proposed project operations and would, therefore, not be CEQA significant.

The Rice Solar Project, as a renewable energy generation facility, is determined by rule to comply with the Greenhouse Gas Emission Performance Standard requirements of SB 1368 (Chapter 11, Greenhouse Gases Emission Performance Standard, Article 1, Section 2903 [b][1]).

MITIGATION MEASURES/PROPOSED CONDITIONS OF CERTIFICATION

No Conditions of Certification related to project greenhouse gas emissions are proposed because the proposed project would create beneficial GHG impacts. The project owner would have to comply with any future applicable GHG regulations formulated by the ARB or the U.S.EPA, such as GHG reporting or emissions cap and trade markets.

BIOLOGICAL RESOURCES

Testimony of Scott D. White

SUMMARY OF CONCLUSIONS

This section summarizes the California Energy Commission staff (staff), Western Area Power Administration (Western), and the Bureau of Land Management (BLM) (hereafter jointly referred to as “agencies”) analysis and staff’s conclusions about the biological impacts of the Rice Solar Energy Project (RSEP). This section also includes Mitigation Measures/Conditions of Certification that meet the Energy Commission’s responsibility to comply with CEQA and serve as recommendations for the Energy Commission to consider in its decision to avoid or reduce the severity of impacts to less than significant and assure conformance with applicable laws, ordinances, regulations and standards (LORS). The identification of relevant and reasonable mitigation measures also conforms to National Environmental Policy Act (NEPA) requirements for BLM’s and Western’s analysis that can be considered in its Record of Decision. This section provides a summary of the analyses contained in this document but is not the decision document for BLM, Western, or the Energy Commission.

The RSEP is a 150-MW solar generation plant, proposed for construction on private land in eastern Riverside County, California. Electrical power generated by the project would be delivered to the transmission grid through an interconnection with the existing Western Parker-Blythe #2 transmission line, southwest of the project site. The facility would consist of a roughly circular solar heliostat field, administrative facilities, and stream channel diversions on approximately 1,470 acres of private land; a 10-mile generator tie-line crossing public and private land; and an interconnection substation (termed ‘switchyard’ in Western documents) on approximately three acres at the tie-in point with Western’s existing transmission line, on public land. A fiber optic overhead ground wire (OPGW) would be installed along the length of the existing Western Parker-Blythe #2 transmission line. Public land on the tie-line alignment and substation site, and throughout the area, is managed by BLM. The solar generator would consist of as many as 17,500 solar-tracking heliostats, or mirrors, that would reflect solar energy to a central solar receiver tower. Each heliostat would be approximately 24 by 28 feet in size. The central receiver tower, including all components, would be 653 feet tall. Electricity would be generated by heating molten salt within the receiver tower; and then pumping it through a steam turbine generator.

The summary provides a general overview of the project impacts to each of the biological resources that are present on the project site, have the potential to be present on the site, or are present off-site and have potential to be indirectly affected by the proposed project. This summary also describes potential mitigation measures that may be employed to avoid or reduce or potentially significant project impacts.

Native Vegetation and Habitat: The RSEP would eliminate or degrade native vegetation and wildlife habitat on the proposed solar generator and interconnector substation sites, and would cause temporary or long-term effects to contiguous habitat north of the solar generator site and along the generator tie-line and Parker-Blythe transmission line alignments. These impacts would affect all plant and wildlife species on the site,

including special status species. Construction of the project would result in the permanent land use conversion of approximately 1,770 acres of habitat to support operation of the solar generator, appurtenant structures, and other project components. The majority of this habitat is creosote bush scrub. There are no data available on vegetation types along the Parker-Blythe #2 transmission line. Staff believes that the majority of the alignment crosses creosote bush scrub similar to that on the project site, but it also appears to cross dunes in Rice Valley and numerous washes, some of which may support desert riparian or microphyll wash woodland.

Although construction would not result in the complete loss of vegetation on the solar generator site, staff considers the construction of security and exclusion fencing (designed to prevent desert tortoise from entering the project site), vegetation mowing, introduction of shade and added moisture from mirror washing, maintenance activity, and risk of invasion by weedy annuals to eliminate or degrade the habitat function of the site for all but the most disturbance-tolerant native species. Disturbance to native vegetation along the transmission line alignments would be limited to access routes, pull sites and tower sites, but mechanical access would cause long-term degradation to affected vegetation and habitat. To minimize project effects on vegetation and habitat, staff has proposed Conditions of Certification **BIO-1** through **BIO-9** (Designated Biologist Selection, Designated Biologist Duties, Biological Monitor Qualifications, Biological Monitor Duties, Designated Biologist and Biological Monitor Authority, Worker Environmental Awareness Program, Biological Resources Mitigation Implementation and Monitoring Plan, Impact Avoidance and Minimization Measures, and Compliance Verification), **BIO-10** (Revegetation and Compensation for Impacts to Native Vegetation), and **BIO-11** (Weed Management Plan). To address specific construction-related impacts to native vegetation and habitat loss, staff has incorporated measures proposed by the applicant and has proposed supplemental measures in Condition of Certification **BIO-16** (Desert Tortoise Habitat Compensation). Staff concludes these measures would reduce impacts of the solar generator facility, generator tie-line, and interconnector substation to vegetation and habitat to a level less than significant. Staff has not determined potential significance of project impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

Rare Plants: One special-status species, chaparral sand verbena, was reported on the RSEP solar generator site and another, Harwood's milk vetch, was reported on the generator tie-line alignment. Other late-season special status species may also occur on the site. There are no available data on special status plant occurrence along the Parker-Blythe #2 transmission line. Staff believes that impacts to chaparral sand verbena would be less than significant under CEQA, and that potentially significant impacts to Harwood's milk vetch can be reduced below a level of significance with the implementation of staff's proposed impact avoidance and minimization measures. These measures are detailed in staff's proposed Conditions of Certification **BIO-1** through **BIO-11**, **BIO-12** (Special-Status Plant Impact Avoidance and Minimization), and **BIO-16**. In addition, **BIO-12** would require additional special-status plant surveys on the Parker-Blythe #2 transmission line and late-season surveys on all project component sites. **BIO-12** provides a strategy to evaluate significance of potential impacts to any special status plants that may be affected by the project, and a series of mitigation measures to reduce those impacts, if any, below a level of significance. Staff concludes that, with mitigation as recommended, impacts of the solar generator site, generator tie-

line, and interconnector substation to rare plants would not be significant. Staff has not determined potential significance of project impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

Common Wildlife and Nesting Birds: Construction of the RSEP would adversely affect common wildlife and nesting birds due to ground disturbance, operation, and permanent exclusion fencing around the perimeter of the solar generator site. Species unable to disperse to surrounding areas will be confined within the project boundaries by the exclusionary fencing, and would be subject to increased risks of road kill and repeated disturbance from human activities during construction and operation. Off-site effects would include noise, lighting, and other disturbance, as well as potential for introduction and spread of weeds and altered off-site hydrology. Transmission line construction and upgrades would degrade habitat at access points (above) and would cause short-term noise and disturbance impacts to wildlife in the construction area. To reduce project effects on common wildlife and nesting birds, staff has proposed Conditions of Certification **BIO-1** through **BIO-11** (above). Among their other requirements, these conditions would require construction scheduling, pre-construction nesting surveys, and other measures to avoid impacts to nesting birds at all construction sites. In addition, staff has recommended Condition of Certification **BIO-16** (Tortoise Habitat Compensation), which also would serve to compensation habitat for common wildlife species and impacts to nesting birds would be avoided by the application of **BIO-13** (Pre-Construction Nest Surveys and Impact Avoidance Measures for Migratory Birds). Staff concludes that, with mitigation as recommended, impacts of the solar generator site, generator tie-line, and interconnector substation to common wildlife would not be significant. Staff has not determined potential significance of project impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

Based on research at a smaller project site using similar technology, operation of the project is expected to result in bird collisions with the heliostat mirrors and incineration at or near focused solar heat at the central tower. Staff cannot quantify the expected impact or assess its significance. Staff has proposed Condition of Certification **BIO-25** (Avian and Bat Protection Plan / Monitoring Operational Impacts Of Solar Collection Facility On Birds), which would require an Avian Protection Plan and a Bird Monitoring Study to monitor the death and injury of birds, and to develop and implement adaptive management measures if those impacts are substantial.

Desert Tortoise: Implementation of the RSEP would result in adverse effects to desert tortoise (federally and State listed as a threatened species). Construction of the proposed project would result in the permanent loss of approximately 1,770 acres of occupied desert tortoise habitat. One desert tortoise was located on the solar generator site during field surveys, and staff estimates that about four tortoises (two adults and one or two juveniles) may live on the site. In addition, about ten tortoise eggs may be expected on the site in a typical year. The transmission line corridors and interconnector substation also are in occupied desert tortoise habitat. To mitigate project impacts to desert tortoises and habitat, staff proposes Conditions of Certification **BIO-1** through **BIO-11** (above), which apply to protection of desert tortoise and other biological resources, and Conditions of Certification **BIO-14** through **BIO-17**, which are specific to desert tortoise. **BIO-14** requires pre-construction clearance surveys and exclusion

fencing, to remove desert tortoises from the solar generator site and prevent tortoises from entering the site in the future. **BIO-15** requires implementing a translocation plan in accordance with US Fish and Wildlife Service (USFWS) and California Department of Fish and Game (CDFG) guidelines, to translocate tortoises to suitable off-site habitat and monitor them. **BIO-16** requires acquisition, protection, and enhancement of compensation desert tortoise habitat. Staff's proposed compensation ratio is 1:1 for habitat loss at the solar generator site and 3:1 for habitat loss on the transmission lines and interconnector substation site, so that a total of 1,988 acres of compensation land would be required. In large part, this requirement may be met through dedication and protection of applicant-owned lands contiguous to the solar generator site. These lands, or other compensation lands, would be protected under a conservation easement and managed in perpetuity as desert tortoise habitat. BLM's requirement for mitigation at a 1:1 ratio, which may include funding for BLM to implement desert tortoise habitat enhancement projects on public land, would also serve to satisfy a portion of the compensation mitigation. Staff recommends a security in the amount \$5,213,088.41 to ensure completion of the habitat compensation requirement. This security includes costs to acquire, protect, and manage the compensation lands in perpetuity, as described in the analysis below and in **BIO-16**. Staff's recommended Condition of Certification **BIO-17** requires management actions to prevent any project-related increase in common raven predation on desert tortoises, as well as contribution on a per-acre basis to a region-wide raven management strategy. This suite of mitigation measures was developed cooperatively by Energy Commission, Western, USFWS, CDFG, and BLM staff. Staff concludes that, with mitigation as recommended, impacts of the solar generator site, generator tie-line, and interconnector substation to desert tortoises would be less than significant pursuant to CEQA and would be fully mitigated as required under the California Endangered Species Act (CESA). Staff has not determined potential significance of project impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

Couch's spadefoot: Couch's spadefoot, a toad-like amphibian, is a BLM sensitive species and CDFG Species of Special Concern that breeds in summer rain pools and burrows below ground throughout most of the year. Its potential for occurrence on the solar generator site is low, but suitable habitat may be found on the Parker-Blythe #2 transmission line alignment. Staff's recommended Condition of Certification **BIO-23** (Couch's Spadefoot Surveys and Breeding Habitat Avoidance) would require seasonal breeding habitat surveys and, as applicable, avoidance of breeding pools during construction of any portion of the project. Staff concludes that this measure would reduce potential project impacts below a level of significance.

Mojave Fringe-Toed Lizard: The Mojave fringe-toed lizard is a BLM sensitive species and California Species of Special Concern. Its primary habitat is fine wind-blown (aeolian) sand deposits such as dunes and sandy patches within scrubby vegetation. It is not expected to occur on the solar generator site, but may occur on the generator tie-line alignment or interconnector substation site, and probably occurs on portions of the Parker-Blythe #2 transmission line alignment. Construction impacts to habitat along the transmission lines would be temporary because aeolian habitat is only sparsely vegetated and post-construction habitat recovery would occur naturally in only a short time. Proposed Condition of Certification **BIO-8** requires that generator tie-line construction and fiber optic OPGW installation on the existing Parker-Blythe #2

transmission line shall avoid any aeolian sand habitat wherever feasible, and, if avoidance is infeasible, site-specific measures will be developed and implemented. Staff concludes that project impacts to Mojave fringe-toed lizard would not be significant.

Burrowing Owl: Construction of the RSEP would result in direct loss of habitat for the burrowing owl (a BLM sensitive species and a California Species of Special Concern). The applicant estimates up to seven burrowing owls occur on the solar generator site and generator tie line alignment. Staff's proposed Condition of Certification **BIO-19** (Burrowing Owl Impact Avoidance and Compensation Measures) provides measures to avoid take or direct impacts to burrowing owls, and to compensate for habitat loss based on the number of single owls or nesting pairs on the site. Habitat compensation may be "nested" within compensation lands required for desert tortoise habitat compensation (**BIO-16**, above). Staff concludes that project impacts of the solar generator site, generator tie-line, and interconnector substation to burrowing owl would be less than significant with incorporation of recommended mitigation. Staff has not determined potential significance of project impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

Golden Eagle: Golden eagle is a BLM sensitive species, and also is protected under the federal Bald and Golden Eagle Protection Act and is ranked as Fully Protected under the California Fish and Game Code. No suitable nesting habitat is found on the solar generator site or generator tie-line alignment; potential nesting habitat along the existing Parker-Blythe #2 transmission line is unknown. Staff has proposed Conditions of Certification **BIO-18** (Pre- Construction Surveys for Golden Eagles) and **BIO-25** (Avian Protection Plan / Monitoring Operational Impacts Of Solar Collection Facility On Birds), to avoid construction-related disturbance to nesting golden eagles along the transmission line. The generator tie-line could present a new collision or electrocution threat to golden eagles. Staff's recommended Condition of Certification **BIO-8** requires that transmission lines, fiber optic lines, and all electrical components shall be designed, installed, and maintained in accordance with guidelines and practices as recommended by the Avian Power Line Interaction Committee's publications to reduce the likelihood of large bird electrocutions and collisions. Project construction would eliminate or degrade approximately 1,770 acres of foraging habitat in the region. This loss could interfere with normal behavior, causing golden eagles to forage more widely and therefore spend less time at or near their nests. This effect could be considered "take," pursuant to the Bald and Golden Eagle Protection Act. Staff's recommended Condition of Certification **BIO-16** (above) requires acquisition, protection, and enhancement of compensation desert tortoise habitat; this habitat also would serve as golden eagle foraging habitat. The solar generator may present a collision or incineration hazard to golden eagles. Staff's recommended Condition of Certification **BIO-25** (above) would evaluate that hazard and implement adaptive management measures as determined necessary. Staff concludes that project impacts of the solar generator site, generator tie-line, and interconnector substation to golden eagle would be less than significant with incorporation of recommended mitigation. Staff has not determined potential significance of project impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

Burrowing mammals: American badgers and desert kit foxes occur throughout the Project area, and construction activities could crush or entomb these burrowing species. Staff's proposed Condition of Certification **BIO-19**, which requires preconstruction surveys and avoidance measures to protect badgers and kit foxes, would avoid these potential impacts.

State and Federal Jurisdictional Waters: The project would directly or indirectly affect numerous state-jurisdictional desert washes and ephemeral channels on the solar generator site and along transmission line corridors. The US Army Corps of Engineers (ACOE) has determined that streambeds on the solar generator and generator tie-line alignment are not within federal jurisdiction as Waters of the US. Streambeds on the Parker-Blythe #2 transmission line have not been delineated and no ACOE jurisdictional determination has been made. Staff's proposed Condition of Certification **BIO-22** (Streambed Impact Minimization and Compensation Measures) requires the acquisition and protection of offsite streambed habitat at a 1:1 ratio for streambed acreage lost on the solar generator site and generator tie-line alignment, and implementation of Best Management Practices to minimize impacts on the site. Habitat compensation for impacts to state-jurisdictional waters may be "nested" within compensation lands required for desert tortoise habitat compensation (**BIO-16**, above). With implementation of staff's proposed Conditions of Certification **BIO-22** staff concludes that project impacts of the solar generator site, generator tie-line, and interconnector substation to state-jurisdictional waters would be less than significant. ACOE has not indicated whether it holds federal jurisdiction over streambeds potentially impacted along the Western Parker-Blythe 161-Kv OPGW Transmission Line or whether such impacts would be authorized under a Nationwide General Permit. Staff has not determined potential state jurisdiction or CEQA significance of project impacts along that alignment, pending additional data.

Wildlife Movement: Construction of the proposed RSEP would have the potential to interrupt wildlife movement through the area. The solar generator site could interrupt potential north-south movement at two suitable wildlife crossings over the nearby California Aqueduct, and the project's perimeter fence could direct animals travelling east-west in the area onto State Highway 62 where risk of vehicle strike would be increased. Staff concludes that the potential impacts to north-south movement would be less than significant and that implementation of staff's recommended Condition of Certification **BIO-21** (Fence locations: Logistics, Lay-down Area and Access Road) would reduce potential impacts to east-west movement below a level of significance.

Cumulative Impacts: Staff concludes that without mitigation, the RSEP would contribute to the cumulatively significant loss of regional resources, including the State and federally threatened desert tortoise and other special status species. Impact avoidance and minimization measures described in staff's analysis and included in the conditions of certification would help reduce impacts to these resources. These compensatory measures are necessary to offset project-related losses, and to assure compliance with State and federal laws such as the federal and State Endangered Species Acts. With the implementation of these measures, staff concludes that the solar generator site, generator tie-line, and interconnector substation contributions to cumulative significant impacts to biological resources would not be considerable. Staff has not determined

potential cumulative significance of project impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

Staff concludes that, with the incorporation of recommended Conditions of Certification **BIO-1** through **BIO-26**, the proposed RSEP solar generator site, generator tie-line, and interconnector substation would be in compliance with applicable Laws, Ordinances, Regulations, and Standards (LORS). Staff has not determined whether the Western Parker-Blythe 161-Kv OPGW Transmission Line, would comply with applicable LORS, pending additional biological data. The assessment of RSEP's effects to Biological resources associated with the telecommunications option to attach a fiber optic cable on the Parker-Blythe #2 Transmission Line will be updated for the CEC's record and the FEIS when additional information is received from the applicant.

INTRODUCTION

This section of the Staff Assessment/Draft Environmental Impact Statement (SA/DEIS) provides staff's analysis of the RSEP's potential impacts to biological resources, including vegetation communities, wildlife and wildlife habitat, and special-status species. This analysis describes the biological resources at the project site and at the locations of ancillary facilities, and evaluates the project's expected impacts to them. This section explains the need for mitigation, evaluates the adequacy of mitigation proposed by the applicant, and specifies additional mitigation measures designed to reduce impacts. It also describes compliance with applicable laws, ordinances, regulations, and standards (LORS) and includes staff's proposed conditions of certification.

This analysis is based, in part, upon information provided in the Rice Solar Energy Project Application for Certification (SR 2009a) and other submittals (SR 2009b; CH2MHill 2010e); responses to staff data requests (CH2MHill 2010a, 2010b, 2010c, and 2010f; Sycamore Environmental Consultants, Inc. 2010), and staff workshops and informational hearings (CH2MHill 2010d); scoping comments (USFWS 2010b); site visits by staff in February and April 2010; communications with representatives from the California Department of Fish and Game (CDFG), Bureau of Land Management (BLM), Western, and the U. S. Fish and Wildlife Service (USFWS); and staff's independent research.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS (LORS)

The applicant will need to abide by the laws, ordinances, regulations, and standards (LORS) during project construction and operation, as listed in **Biological Resources Table 1**.

**Biological Resources Table 1
Laws, Ordinances, Regulations, and Standards (LORS)**

Applicable LORS	Description
FEDERAL	
Federal Endangered Species Act (Title 16, United States Code, section 1531 et seq., and Title 50, Code of Federal Regulations, part 17.1 et seq.)	Designates and provides for protection of threatened and endangered plant and animal species and their critical habitat. Take of a federally-listed species, as defined in the Act, is prohibited without incidental take authorization, which may be obtained through Section 7 consultation (between federal agencies) or a Section 10 Habitat Conservation Plan.
Migratory Bird Treaty Act (Title 16, United States Code, sections 703 through 711)	Makes it unlawful to take or possess any migratory bird (or any part of such migratory bird including active nests) as designated in the Migratory Bird Treaty Act unless permitted by regulation (e.g., duck hunting).
Clean Water Act (Title 33, United States Code, sections 1251 through 1376, and Code of Federal Regulations, part 30, section 330.5(a)(26))	Requires the permitting and monitoring of discharges to surface water bodies. Section 404 requires a permit from the U.S. Army Corps of Engineers (USACE) for a discharge from dredged or fill materials into waters of the U.S., including wetlands. Section 401 requires a permit from a regional water quality control board (RWQCB) for the discharge of pollutants. By federal law, every applicant for a federal permit or license for an activity that may result in a discharge into a California water body, including wetlands, must request State certification that the proposed activity will not violate State and federal water quality standards.
Bald and Golden Eagle Protection Act (Title 16, United States Code section 668)	Provides for the protection of the bald eagle and the golden eagle by prohibiting, except under certain specified conditions, the take, possession, and commerce of such birds. The 1972 amendments increased penalties for violating provisions of the act or regulations issued pursuant thereto and strengthened other enforcement measures. Rewards are provided for information leading to arrest and conviction for violation of the act.
Eagle Act (Title 50, Code of Federal Regulations, section 22.26)	Would authorize limited take of bald and golden eagles under the Eagle Act, where the taking is associated with, but not the purpose of activity, and cannot practicably be avoided.
Eagle Act (Title 50, Code of Federal Regulations, section 22.27)	Would provide for the intentional take of eagle nests where necessary to alleviate a safety hazard to people or eagles; necessary to ensure public health and safety; the nest prevents the use of a human-engineered structure, or; the activity, or mitigation for the activity, will provide a net benefit to eagles. Only inactive nests would be allowed to be taken except in the case of safety emergencies.
California Desert Conservation Area Plan 1980, as amended (reprinted in 1999)	Administered by the BLM, the California Desert Conservation Area (CDCA) Plan requires that proposed development projects are compatible with policies that provide for the protection, enhancement, and sustainability of fish and wildlife species, wildlife corridors, riparian and wetland habitats, and native vegetation resources.
California Desert Protection Act of 1994	An Act of Congress which established 69 wilderness areas, the Mojave National Preserve, expanded Joshua Tree and Death Valley National Monuments and redefined them as National Parks. Lands transferred to the National Park Service were formerly administered by the BLM and included significant portions of grazing allotments, wild horse and burro Herd Management Areas, and Herd Areas.

Applicable LORS	Description
Northern and Eastern Colorado Desert Coordinated Management Plan (NECO)	The BLM produced the Northern and Eastern Colorado Desert Coordinated Management Plan (NECO) as an amendment to the 1980 CDCA Plan (BLM 2002). The NECO is a federal land use plan amendment that resolves issues of resource demands, use conflicts, and environmental quality in the 5.5-million acres planning area located primarily within the Sonoran Desert in the southeastern corner of California. NECO provides reserve management for the desert tortoise, integrated ecosystem management for special status species and natural communities for all federal lands, and regional standards and guidelines for public land health for BLM lands (BLM and CDFG 2002).
Executive Order 11312	Prevent and control invasive species.
Desert Tortoise (Mojave Population) Recovery Plan (USFWS 1994) and Draft Revised Recovery Plan (USFWS 2008a)	Describes a strategy for recovery and delisting of the desert tortoise.
STATE	
California Endangered Species Act of 1984 (Fish and Game Code, sections 2050 through 2098)	Protects California's rare, threatened, and endangered species. Take of a State-listed species, as defined in the Act, is prohibited without an Incidental Take Permit.
Protected furbearing mammals (California Code of Regulations, Title 14, section 460)	Fisher, marten, river otter, desert kit fox and red fox may not be taken at any time.
California Code of Regulations (Title 14, sections 670.2 and 670.5)	Lists the plants and animals of California that are declared rare, threatened, or endangered.
Fully Protected Species (Fish and Game Code, sections 3511, 4700, 5050, and 5515)	Designates certain species as fully protected and prohibits the take of such species or their habitat unless for scientific purposes (see also California Code of Regulations, Title 14, section 670.7).
Nest or Eggs (Fish and Game Code section 3503)	Protects California's birds by making it unlawful to take, possess, or needlessly destroy the nest or eggs of any bird.
Birds of Prey (Fish and Game Code section 3503.5)	Birds of prey are protected in California making it "unlawful to take, possess, or destroy any birds of prey (in the order Falconiformes or Strigiformes)."
Migratory Birds (Fish and Game Code section 3513)	Protects California's migratory birds by making it unlawful to take or possess any migratory nongame bird as designated in the Migratory Bird Treaty Act or any part of such migratory nongame birds.
Nongame mammals (Fish and Game Code section 4150)	Makes it unlawful to take or possess any non-game mammal or parts thereof except as provided in the Fish and Game Code or in accordance with regulations adopted by the commission.
Significant Natural Areas (Fish and Game Code section 1930 et seq.)	Designates certain areas such as refuges, natural sloughs, riparian areas, and vernal pools as significant wildlife habitat.
Designated Ecological Reserves (Fish and Game Code section 1580 et seq.)	The CDFG commission designates land and water areas as significant wildlife habitats to be preserved in natural condition for the general public to observe and study.

Applicable LORS	Description
California Environmental Quality Act (CEQA), CEQA Guidelines section 15380	CEQA defines rare species more broadly than the definitions for species listed under the State and federal Endangered Species Acts. Under section 15830, species not protected through State or federal listing but nonetheless demonstrable as “endangered” or “rare” under CEQA should also receive consideration in environmental analyses. Included in this category are many plants considered rare by the California Native Plant Society (CNPS) and some animals on the CDFG’s Special Animals List.
Warren Alquist Act of 2005 (Public Resources Code sections 25000 et seq.)	A CEQA-equivalent process implemented by the Energy Commission.
Streambed Alteration (Fish and Game Code sections 1600 et seq.)	Regulates activities that may divert, obstruct, or change the natural flow or the bed, channel, or bank of any river, stream, or lake in California designated by CDFG in which there is at any time an existing fish or wildlife resource or from which these resources derive benefit. Impacts to vegetation and wildlife resulting from disturbances to waterways are also reviewed and regulated during the permitting process.
California Native Plant Protection Act of 1977 (Fish and Game Code section 1900 et seq.)	Designates State rare, threatened, and endangered plants.
California Desert Native Plants Act of 1981 (Food and Agricultural Code section 80001 et seq. and California Fish and Game Code sections 1925-1926)	Protects non-listed California desert native plants from unlawful harvesting on both public and private lands in Imperial, Inyo, Kern, Los Angeles, Mono, Riverside, San Bernardino, and San Diego counties. Unless issued a valid permit, wood receipt, tag, and seal by the commissioner or sheriff, harvesting, transporting, selling, or possessing specific desert plants is prohibited.
Porter-Cologne Water Quality Control Act	Regulates discharges of waste and fill material to waters of the State, including “isolated” waters and wetlands.
LOCAL	
Riverside County General Plan: Land Use and Multipurpose Open Space Elements of the County General Plan (County of Riverside 2003)	Contains specific policies to preserve the character and function of open space that benefits biological resources. It also contains specific policies and goals for protecting areas of sensitive plant, soils and wildlife habitat and for assuring compatibility between natural areas and development. The RSEP area and most of eastern Riverside County is designated as Open Space Conservation in the General Plan. Although the RSEP is not within one of the 19 area plans contained within the General Plan, it is addressed in the Eastern Riverside County Desert Areas (Non-Area Plan).

DESERT RENEWABLE ENERGY CONSERVATION PLAN – INTERIM PLANNING

In addition to the federal, state, and local LORS summarized above, federal and state agencies are currently collaborating to establish joint policies and plans to expedite development of California’s utility scale renewable energy projects. On October 12, 2009, the State of California and the U.S. Department of Interior entered into a Memorandum of Understanding (MOU) on renewable energy, building on existing efforts by California and its federal partners to facilitate renewable energy development in the state. The MOU stems from California and Department of Interior energy policy directives, and California’s legislative mandate to reduce greenhouse gases to 1990

levels by 2020, and meet the goal of 33% of California's electricity production from renewable energy sources by 2020.

The California-Department of Interior MOU expands on several MOUs issued in 2008 to establish the activities of the California Renewable Energy Action Team (REAT). The REAT was established with California Executive Order S-14-08 (issued November 18, 2008), to *“establish a more cohesive and integrated statewide strategy, including greater coordination and streamlining of the siting, permitting, and procurement processes for renewable generation....”*

The Energy Commission and CDFG are the primary state collaborators in the REAT, operating under a November 18, 2008 MOU between the two agencies to create a “one-stop process” for permitting renewable energy projects under their joint permitting authority. The BLM and the USFWS also participate in the REAT under a separate MOU signed in November 2008, which outlines the state and federal cooperation of the group. The October 12, 2009 MOU between California and the Department of Interior reiterates several tasks of the REAT provided for in S-14-08 and the Energy Commission-Fish and Game MOU.

The REAT's primary mission is to streamline and expedite the permitting processes for renewable energy projects in the Mojave and Colorado Desert ecoregions within the State of California, while conserving endangered species and natural communities at the ecosystem scale. To accomplish this goal the REAT Agencies are developing a Desert Renewable Energy Conservation Plan (DRECP), a science-based process for reviewing, approving, and permitting renewable energy applications in California. Once the DRECP is complete, anticipated in late 2012, the plan will provide tools to expedite coordination of federal and state endangered species act permitting. The DRECP will also offer a unified framework for state and federal agencies to oversee mitigation actions, including land acquisitions, for listed species. The REAT Agencies recognize that some renewable energy projects are scheduled to be approved prior to completion of the DRECP. Section 8.9 of the October 2009 Draft Planning Agreement for the DRECP <www.energy.ca.gov/2009publications/...2009.../REAT-1000-2009-034.PDF> provides explicit guidance for such interim projects, and directs the REAT Agencies to ensure that permitting for these projects:

- Be consistent with the preliminary conservation objectives for the DRECP;
- Not compromise successful completion and implementation of the DRECP;
- Facilitate Federal Endangered Species Act, California Endangered Species Act, National Environmental Policy Act, and California Environmental Quality Act compliance; and
- Not be unduly delayed during preparation of the DRECP.

REAT Account and SB 34

The REAT agencies recently signed a Memorandum of Agreement (MOA) to establish a REAT Account that may be used by project developers to deposit funding for specified mitigation for approved renewable energy projects in the Mojave and Colorado Desert region of southern California (the MOA is available at <www.energy.ca.gov/33by2020>).

For each project using the REAT Account an individual subaccount would be established for project specific tracking, compliance and accounting purposes. The subaccount would include a list of the specific mitigation actions, the cost, a timeframe for carrying out the actions, and identify which of the REAT agencies would be responsible for requiring and coordinating the mitigation actions. The National Fish and Wildlife Foundation (NFWF) would manage the subaccount on behalf of the REAT agencies, and at their direction would disburse mitigation funding to satisfy mitigation requirements for impacts to biological resources. NFWF is a charitable non-profit corporation established in 1984 by the federal government to accept and administer funds to further the conservation and management of fish, wildlife, plants and other natural resources <www.nfwf.org>. Use of the REAT Account would not change any of the requirements a project proponent must fulfill in order to comply with applicable State and Federal environmental laws governing the permitting of the projects.

The REAT Account will also aid project proponents in carrying out contracting and construction activities in a timely manner per requirements for American Recovery and Reinvestment Act of 2009 (ARRA) funding. The SBX8 34 legislation that was recently signed into law by the Governor created a \$10 million loan that provides for advanced mitigation habitat purchases. This advanced mitigation can be used by a qualifying solar renewable energy project to receive credit for implemented mitigation after a project proponent pays into the Renewable Energy Development Fee Trust Fund that was created by the SBX8 34 legislation (SBX8 34 Trust Fund). Funds in the MOA REAT Account and the SBX8 34 Trust Fund are similar in that renewable energy project proponents pay into accounts set up to receive project-specific mitigation funds, and a third party entity implements the mitigation actions. Staff's proposed Condition of Certification **BIO-26** provides an opportunity for the Applicant to fulfill their mitigation obligations by depositing funds into the SB 34 Trust Fund.

METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

The analysis of proposed Project effects must comply with both CEQA and NEPA requirements given the respective power plant licensing and land jurisdictions of the Energy Commission and Western. CEQA requires that the significance of individual effects be determined by the Lead Agency, but the use of specific significance criteria is not required by NEPA.

CEQA requires a list of criteria that are used to determine the significance of identified impacts. A significant impact is defined by CEQA as “a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project” (State CEQA Guidelines Section 15382).

The following are the Energy Commission's significance criteria for biological resources. These criteria are based on Appendix G of the CEQA Guidelines (CCR 2006) and performance standards or thresholds identified by Energy Commission staff. The determination of whether a project has a significant effect on biological resources is based on the best scientific and factual data that staff could review for the project. In

this analysis the following impacts to biological resources are considered significant if the project would result in:

- A substantial adverse effects to plant species considered by the California Native Plant Society (CNPS), CDFG, or USFWS to be rare, threatened, or endangered in California or with strict habitat requirements and narrow distributions; a substantial impact to a sensitive natural community (i.e., a community that is especially diverse; regionally uncommon; or of special concern to local, state, and federal agencies);
- A substantial adverse effect to wildlife species that are federally-listed or state-listed or proposed to be listed; a substantial adverse effect to wildlife species of special concern to CDFG, candidates for state listing, or animals fully protected in California;
- Substantial adverse effects on habitats that serve as breeding, foraging, nesting, or migrating grounds and are limited in availability or that serve as core habitats for regional plant and wildlife populations;
- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites;
- Substantial adverse effect on important riparian habitats or wetlands and any other “Waters of the U.S.” or state jurisdictional waters; and
- Conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan.

In contrast to CEQA, “significantly” as used in NEPA requires considerations of both context and intensity (40 CFR 1508.27). According to the NEPA Regulations adopted by the President’s Council on Environmental Quality (CEQ) (40 CFR 1500-1508), context means the affected environment in which a proposed action would occur; it can be local, regional, national, or all three, depending upon the circumstances. In determining the intensity of an impact, the following factors are considered:

- Adverse effects of a project even though the overall proposed action is beneficial;
- Effects on public health or safety;
- Unique characteristics of the geographic area, such as historic resources, park lands, prime farmland, wetlands, wild and scenic rivers, ecologically critical areas;
- Degree of controversy;
- Degree of highly uncertain effects or unique or unknown risks;
- Precedent-setting effects;
- Cumulative effects;
- Adverse effects on scientific, cultural, or historical resources;
- Adverse effects on endangered or threatened species or designated critical habitat (pursuant to the Endangered Species Act); and
- Violations of federal, state, or local environmental law.

For NEPA, thresholds serve as a benchmark for determining if a project action would result in a significant adverse environmental impact when evaluated against the baseline. NEPA requires that an Environmental Impact Statement (EIS) be prepared when the proposed federal action (project) as a whole has the potential to “significantly affect the quality of the human environment.”

PROPOSED ACTION ALTERNATIVE / PROPOSED PROJECT

SETTING AND EXISTING CONDITIONS

Regional Setting

The proposed RSEP project site is located approximately 34 miles northwest of the city of Blythe, just south of State Route 62 (SR-62). The project consists of a solar generation site on private land and a generator tie-line and interconnection substation, primarily on BLM-managed lands within the Northern and Eastern Colorado Desert (NECO) planning area. Several designated wilderness areas managed by the BLM occur near the project area. The proposed solar site is located approximately 2 miles south of the Turtle Mountains Wilderness, 5 miles northeast of the Palen/McCoy Wilderness, 3 miles north of the Rice Valley Wilderness, 6 miles west of the Chemehuevi Desert Wildlife Management Area (DWMA) and the Chemehuevi desert tortoise critical habitat unit, and 9 miles northwest of the Riverside Mountains Wilderness. The proposed generator tie-line interconnection point is within a mile from the Rice Wilderness and immediately adjacent to the Riverside Mountains Wilderness.

The project site is located within the Rice Wildlife Habitat Management Area (WHMA) established in BLM's 2002 Northern and Eastern Colorado Desert Coordinated Management Plan (NECO). This WHMA was designated to provide management for the sand dune habitat for the Mojave fringe-toed lizard and to provide wildlife connectivity between the Chemehuevi Desert Wildlife Management Area/Turtle Mountains Wilderness to the north and Palen-McCoy and Rice Valley wildernesses to the south. This designation applies formally only to BLM-managed lands (i.e., the generator tie-line alignment) but reflects biological resource values that also are applicable to the proposed solar generator site, on private land.

The project area lies in the Rice Valley within the northern portion of the Colorado Desert, which is part of the larger Sonoran Desert that encompasses portions of California, Arizona, and the Mexican states of Sonora, Baja California, and Baja California Sur. The project area lies in a transition zone between the Colorado Desert and the Mojave Desert. The Colorado Desert is often referred to as California's “Low Desert.” This desert experiences more summer precipitation than the northern deserts, and although annual precipitation is low overall, a significant portion of it falls during August and September, usually as flashy thunderstorms (Schoenherr 1992). In contrast, the Mojave Desert is referred to as California's “High Desert” and experiences a slightly different climatic regime than the Colorado Desert. It lies in the rain shadow of the Sierra Nevada and Transverse Mountain ranges, and receives most precipitation during winter months, although summer thunderstorms also occur (Schoenherr 1992). The average annual precipitation recorded at Iron Mountain, approximately 18 miles to the

northwest of the proposed solar field, is 3.4 inches and average monthly temperatures at this location generally range between 43 and 108°F (WRCC 2010).

The Rice Valley is a dry, shallow basin with a north-south orientation, bounded by the Turtle Mountains to the north and the Big Maria Mountains to the south. The edges of the Valley are more weakly defined to the west by the Arica Mountains and to the east by the West Riverside Mountains. These mountain ranges are rugged and provide habitat for special-status species such as Nelson's bighorn sheep (*Ovis canadensis nelsoni*), and various plant communities including desert dry wash woodlands (SR 2009a). The rugged mountain areas, lowland valleys, and dunes provide a diversity of topographical features and habitat for a variety of plant and animal species. Dune areas are often occupied by rare and endemic plant and animal species. The sand dunes along the southern end of the Valley support specialists such as the Mojave fringe-toed lizard (*Uma scoparia*), and the entire valley provides foraging habitat for a number of species including golden eagle (*Aquila chrysaetos*) and prairie falcon (*Falco mexicanus*). The Valley is dominated by Sonoran desert scrub interrupted by a large sand dune complex that stretches from Cadiz to Ward Valley.

Although considered within the West Basin of the Colorado River, which drains primarily into the Salton Sea Trough, Rice Valley is a sink with no broader hydrological connectivity. Rice Valley has a small watershed and lacks any major washes. There are no perennial surface water sources within the sink and there is no evidence that a lake ever formed in the Valley during wetter climatic periods (SR 2009a).

Current human activity in the Rice Valley is primarily concentrated at the north end of the Valley, where an east-west linear corridor of transportation and infrastructure features, the Colorado River Aqueduct, the Arizona-California Railroad, and SR-62, are located. These three parallel features present a major north-south barrier to wildlife passage and interrupt local hydrology (SR 2009a).

Other than the development in the northern part of the Valley and ephemeral domestic sheep grazing, today the Rice Valley appears to be subject to light use by humans. Much of the Valley is now contained within the Rice Valley Wilderness Area, but the Valley presents few recreational opportunities other than self-contained day use or camping, vehicle recreation, or spring season wildflower viewing due to the lack of water, developed recreational sites, sparse vegetation, and mostly level topography (SR 2009a).

Project Area

The project area as addressed throughout this section consists of sites proposed for use as RSEP solar fields; all associated buildings and other permanent site facilities within or adjacent to the solar field footprint; the 10-mile generator tie-line; the interconnection substation; and all areas to be temporarily disturbed by construction or other aspects of the project. The solar field, solar receiver tower, power generation equipment, and associated facilities are collectively termed the solar generator site throughout this section. The project area, including the solar generator site, generator tie-line, and interconnection substation, is primarily open, undeveloped or historically developed land within the Colorado Desert. The applicant owns a 3,324-acre holding in

Rice Valley, consisting of six parcels. Within this holding, the RSEP solar field site would be located on a new 2,560-acre square-shaped parcel that would be created by merging four existing assessor's parcels (CH2MHill 2010c). The heliostat field and most other permanent facilities would be located in a circular area encompassing 1,410 acres of the property, to be enclosed within a permanent boundary fence (SR 2009a). During operation, most project facilities, including parking areas, administration buildings, water treatment system, a 230-kV switchyard, the approximately 1,316-acre heliostat field and associated power generation structures, and evaporation ponds would be contained within this fenced boundary. This entire solar generator site would be permanently disturbed by project construction and operation.

Other project facilities, including the generator tie-line, distribution line, drainage diversion channels surrounding the north side of the solar field, temporary logistics and lay-down area to be located between the heliostat field and SR-62, the fiber optic (OPGW) along the Western Parker-Blythe #2 transmission line, and a short portion of the site's main access road, would be outside the security fence. Some of these areas would be permanently disturbed by the proposed project, while others, including the logistics/lay-down areas and transmission line tower construction sites, would be temporarily disturbed during construction. However, due to the slow post-disturbance recovery of desert soils and vegetation, staff considers these temporary disturbances to be long-term.

The proposed logistics and lay-down area is on 60 acres, immediately south of SR-62 and outside the proposed heliostat field. During construction, all logistics, laydown, and parking would be contained within this temporarily fenced area. This area would be temporarily disturbed, though staff regards temporary construction disturbances in the desert environment as having long-term impacts to vegetation and habitat values (see **Construction Impacts to Vegetation**, below). Additional long-term disturbance areas would include transmission tower construction sites, pull sites, and other logistics, staging, and lay-down areas along the proposed new transmission line, distribution line, and the Western Parker-Blythe #2 transmission line. Staff estimates total long-term disturbance resulting from temporary construction impacts as 287 acres. Staff estimates the total long-term and permanent project disturbance would be approximately 1,760 acres. Acreages of these project facilities are summarized below in **Biological Resources Table 2**.

**Biological Resources Table 2.
Summary of Project Components and Acreages¹**

Project component	Applicant-owned land	Private land (other)	Public (BLM) land	Total
Total contiguous applicant holdings (six parcels)	3,324 acres	n/a	n/a	3324 acres
Project site (four parcels, to be merged into one)	2,560 acres	n/a	n/a	2560 acres
Solar generator site, including permanent facilities within perimeter fence	1,410 acres	0	0	1410 acres
Permanent stream channel diversions (outside perimeter fence) ²	35-60 acres			35-60 acres
Long-term construction-phase disturbance (parking, lay-down, workforce RV camp, and logistics)	60 acres	0	0	60 acres
Permanent new access and maintenance road for transmission line (24 ft. wide x 4.6 or 5.4 miles) ³	0		14-16 acres	14-16 acres
Long-term disturbance for new distribution line (existing line to perimeter of solar generator site)	Unkn.		Unkn.	Unkn.
Long-term disturbance for new transmission line towers and pull sites ⁴	10 acres	10 acres	80 acres	100 acres
Permanent disturbance for interconnector substation			3 acres	3 acres
Long-term disturbance for ground line construction on existing Western 161 kV Transmission Line ⁵		Unkn.	Unkn.	127 acres
Total Project disturbance area	1,515-1,540 acres	10 acres +	97-99 acres +	1,749-1,776 acres

1. Data from the Application for Certification (SR 2009a) unless otherwise noted.

2. Staff estimate based on CH2MHill 2010g.

3. Total generator tie- line right of way = 150 acres (Rice Solar Energy 2010). Staff estimates road disturbance as 24-foot width x length of road; length is reported as 4.6 miles in SR 2009a, and as 5.4 miles in CH2MHill 2010d.

4. Staff estimates 90 towers and 10 pull sites, each site approximately one acre; approximately 80% of tower and pull sites would be on BLM land.

5. Estimate provided by Western (pers. comm. W. Werner).

The proposed project site is located on a gently sloping alluvial fan, ranging in elevation from approximately 750 to 920 feet (229 to 280 m) above mean sea level (SR 2009a). The proposed solar field is bordered at the north by SR-62. North of the highway, and parallel to it, are the Arizona-California Railroad line and the Colorado River Aqueduct. Adjacent land to the west is owned by the applicant, and BLM-managed lands abut the project site to the south and east (SR 2009a).

The proposed RSEP solar field site was used as a military supply and training base during World War II. The former Rice Army Airfield was constructed as part of the Desert Training Center and used as a military training airfield from 1942 to 1944. The

airfield originally consisted of two oiled 5,000-foot runways and numerous aircraft hardstands extending beyond the runways to the southeast and southwest. Although the aboveground structures have been removed and some vegetation has become reestablished, the “V”-shaped runway and general layout of the former Rice Army Airfield remain apparent in aerial photography. Following military use between 1942 and 1944, the land has been in private holding and was subsequently used as a private airport; however, the site was abandoned sometime between 1954 and 1958 (SR 2009a).

A new 230-kV generator tie-line with a fiber optic communication cable would interconnect to Western’s 161-kV/230-kV Parker-Blythe #2 transmission line. The generator tie-line would extend for 10.0 miles from the RSEP fenceline southeast to a new interconnection substation (termed ‘switchyard’ in Western documents). The new generator tie-line would be located primarily on BLM land and would include the establishment of approximately 5.4 miles of new dirt service roadway (CH2MHill 2010d) and a new 300 x 400 foot substation at the point of interconnection. The remaining 4.6 miles of generator tie-line would be located adjacent to an existing dirt road (Rice Valley Road), which would serve as its access road (CH2MHill 2010d). The fiber optic OPGW would be installed along the length of the existing Western Parker-Blythe #2 transmission line, necessitating access road improvements along the alignment; construction equipment access to 489 existing wooden transmission line towers in undeveloped (largely BLM) land; and 21 two-acre tensioning (pull) sites (Western 2010).

Proposed Project

The proposed project consists of the construction and operation of a 150-MW solar generation plant and associated facilities on private land. The permanent facility would encompass approximately 1,445 to 1,470 acres (based on information provided by the applicant and additional staff estimates; see **Biological Resources Table 2**), and an additional 60 acres would be disturbed on site for temporary construction-related facilities. A 10-mile generator tie-line would be constructed to connect to Western’s existing Parker-Blythe #2 transmission line. The tie-line would be located primarily on public land managed by the BLM, and an interconnection substation would be constructed on approximately 2.8 acres BLM-managed land at the point of interconnection to the Parker-Blythe #2 transmission line. The design rating of Western’s existing system is for 230 kilovolts (kV), though it currently operates at only 161 kV. The new generator tie-line and interconnection substation would be operated at the present voltage level of Western’s system, with flexibility to be upgraded to 230 kV in the future. The generator tie-line would require construction of 5.4 miles of new unpaved access road and use of 4.6 miles of existing dirt roads.

Major components of the proposed project include the following:

- As many as 17,500 solar-tracking heliostats, or mirrors, each 672 square feet in area, in a circular array that will reflect solar energy to the solar receiver tower. Each heliostat would be approximately 24 by 28 feet in size, and each would be mounted on a 12-foot-tall pedestal;
- A 538-foot-high concrete solar receiver tower with a 100-foot-tall solar receiver and 15-foot crane (for a total height of 653 feet);

- A liquid salt circulation and storage system consisting of hot (approximately 1,050°F) and “cold” (approximately 550°F) salt storage tanks, capable of storing 70 million pounds (4.4 million gallons) of liquid salt (sodium nitrate/potassium nitrate mixture);
- Three evaporation ponds, approximately 5 acres each, to process wastewater discharge from the water treatment system, steam turbine cooling system, other on-site industrial uses, and oil/water separator
- Related generation equipment and administrative facilities on the solar generator site;
- A 30-acre-foot capacity stormwater detention basin consisting of the portion of the heliostat field along its southern boundary and the southern boundary road berm;
- West and east diversion channels around the upslope (north) perimeter of the solar field, to be located outside the perimeter fence, with dissipaters at the downstream ends (from preliminary drawings, staff estimates total acreage at 35-60 acres);
- Extension of the existing 12-kV electrical distribution line from a location 175 feet east of the project parcel boundary for approximately 1.1 miles to the facility fenceline to supply electrical power to project ancillary facilities ;
- Perimeter and internal access roads;
- Perimeter fencing;
- A 10.0-mile long generator tie-line to connect with Western’s existing Parker-Blythe #2 transmission line;
- A new interconnection substation (estimated as approximately 2.8 acres) to be located at the point of interconnection with Western’s existing transmission line; and
- A fiber optic overhead ground wire (OPGW) along the length of the existing Western Parker-Blythe #2 transmission line (see **Transmission System Engineering Appendix A Figure 1**).

Water Supply

The applicant proposes to obtain water for project use from two onsite wells. One of the onsite wells is an existing well that would be modified for use. A second new well would be drilled. RSEP’s maximum total project water consumption would be approximately 180 acre-feet per year (SR 2009a).

Drainage, Erosion, and Sediment Control

The proposed RSEP would include the construction of a water diversion and sediment control facility to divert water and limit runoff and erosion on the project site. Offsite stormwater would be directed around the solar site and onsite runoff would be directed toward detention basins located in the southern portion of the heliostat field. A dirt, gravel, or paved perimeter access road would surround the heliostat field. It would be built on a raised berm which would serve to protect the heliostat field from scouring flows originating upslope and to impound runoff originating on-site. On the northern (upslope) perimeter, an unlined diversion channel would surround the site and perimeter road to direct stormwater around the solar site. Run-off originating within the heliostat

field would be impounded onsite in an approximately 30-acre-foot detention basin behind the perimeter road berm at the southern (downslope) margin of the heliostat field. The detention basin would be designed to percolate, evaporate, or drain the flows (at pre-existing flow rates) from the site as well as act as a sediment control location (SR 2009a, Appendix 5.15B).

Evaporation Ponds

Three evaporation ponds, approximately 5 acres each, would be required to process wastewater discharge from the water treatment system, cooling system, other on-site industrial uses, and oil/water separator. Each evaporation pond would have an average basin depth of six feet, with side slopes of 3:1 (horizontal: vertical) and a minimum freeboard (i.e., basin depth above maximum operational waterline) of two feet (CH2MHill 2010a; Appendix 5.15B of SR 2009a). The evaporation ponds would be located just south of the detention basin on the south end of the heliostat field, and would be surrounded by berms to prevent stormwater from entering the ponds (Appendix 5.15B of SR 2009a).

Construction Schedule, Workforce, Access, and Laydown Areas

Construction of the RSEP from site preparation and grading to commercial operation is expected to require approximately 30 months, and is expected to take place from the first quarter of 2011 to the third quarter of 2013 (SR 2009a). Construction activities would generally be scheduled between 0500 and 1900, Monday through Saturday. Additional hours, up to 24 hours per day, 7 days per week, may be necessary to make up schedule deficiencies, to work around extreme mid-day heat during summer months and other extreme weather, or to complete critical construction activities. The size of the onsite construction workforce would range from a minimum of 29 to a maximum of 438 (SR 2009a).

The project would have one temporary logistics and lay-down area, located at the north end of the project site between SR-62 and the heliostat field. This area would contain a temporary 11-acre parking area, 31-acre RV trailer park for workers, and an 18-acre construction office, laydown, and heliostat assembly area. This temporary logistics area would be contained within temporary fencing during construction. The project site would be accessed directly from SR-62 (SR 2009a).

Operations/Maintenance Activities

The RSEP is designed for an operating life of 30 years and is expected to operate (generate electricity) an average of 8.4 hours per day, 7 days a week throughout the year, with the exception of scheduled shut-downs for maintenance. The applicant expects that the project would be operated with a staff of approximately 47 full-time employees. Operations activities would occur 7 days per week, 24 hours per day. Maintenance activities would occur Monday through Friday, up to 10 hours per day, with additional days and hours as needed to support plant outages (SR 2009a).

The heliostats would be regularly washed to keep mirror surfaces free of dust buildup to optimize solar energy potential. Heliostat washing would require the use of approximately 31 acre-feet of water per year, based on washing each heliostat 37 times

per year. Heliostat washing would occur on a 5 day per week schedule using 2 crews operating 8 hours per day (SR 2009a).

RSEP’s maximum total projected water consumption would be approximately 180 acre-feet per year, and would mainly be used to provide water for washing heliostats, steam cycle makeup, water treatment system discharge, and other uses such as wet surface air cooler, service water, and quench water (SR 2009a).

Vegetation and Wildlife

Plant Communities

Most of the solar generator site is covered by creosote bush scrub. A few small portions of the site support white bursage scrub (**Biological Resources Figure 1**). Near the northern margin of the project site, outside the proposed project footprint, there are linear patches of smoke tree woodland, along ephemeral channels immediately downstream from breaches in the unmaintained levees that protected the former Rice Airfield. The descriptions below are based on staff’s field visits to the site and the applicant’s vegetation maps and descriptions, which covered the entire 2,560 acre parcel proposed for the solar generator site, as well as a 1000-foot wide corridor along the generator tie-line alignment (of CH2MHill 2010a). **Biological Resources Table 3** (below) summarizes project disturbance acreage by vegetation type.

**Biological Resources Table 3.
Summary of Project Disturbance Acreage by Vegetation Type¹**

Vegetation Type	Solar Generator Site and Contiguous Facilities	Transmission lines and Interconnector Substation	Total
Creosote bush scrub	1,422-1,447 acres	107-109 acres	1,529-1,556 acres
White bursage scrub	87 acres	0	87 acres
Smoke tree woodland	0	0	0
Unvegetated (concrete pad)	6 acres	0	6 acres
Unmapped disturbance (existing 161-kv Parker-Blythe #2 transmission line)	0	127 acres	127 acres
Total Project disturbance area¹	1,515-1,540 acres	234-236 acres	1,749-1,776 acres

1. Does not include Distribution Line or Fiber Optic OPGW

Creosote bush scrub (*Larrea tridentata*-*Ambrosia dumosa* shrubland, per. Sawyer et al. 2009) covers most of the site (see Figure DR70-1 of CH2MHill 2010a). It is dominated by creosote bush (*Larrea tridentata*) and white bursage (*Ambrosia dumosa*). In many areas of the study area, white bursage has greater absolute cover than creosote bush, but not sufficient for these areas to be classified as *Ambrosia dumosa* shrubland (see below). Other shrubs present at low abundance are burrobrush (*Hymenoclea salsola* var. *salsola*), brittlebush (*Encelia farinosa*), and white rhatany (*Krameria grayi*). Common species in the herb layer are white tackstem (*Calycoseris wrightii*), pebble pincushion (*Chaenactis carphoclinia* var. *carphoclinia*), desert dandelion (*Malacothrix glabrata*), devil’s lettuce (*Amsinckia tessellata*), Nevada cryptantha (*Cryptantha nevadensis*), broad-fruited comb-bur (*Pectocarya platycarpa*), Sahara mustard

(*Brassica tournefortii*), rattlesnake weed (*Chamaesyce albomarginata*), desert lantern (*Camissonia boothii* ssp. *condensata*), desert plantain (*Plantago ovata*), and Mediterranean grass (*Schismus barbatus*). Creosote bush scrub is not ranked by CDFG (2003) as a special-status vegetation community.

White bursage scrub (*Ambrosia dumosa* shrubland, per. Sawyer et al. 2009) covers approximately 87 acres in the northwestern portion of the proposed solar generator site (see Figure DR70-1 of CH2MHill 2010a). This vegetation is dominated by white bursage, although creosote bush is also common. It is distinguished from creosote bush scrub by relative greater cover of white bursage (Sawyer et al. 2009). Burrobrush is also present at low cover levels in the community. The herb layer is similar to that described above for creosote bush scrub. White bursage scrub is not ranked by CDFG (2003) as a special-status vegetation community.

Smoke tree woodland (*Psorothamnus spinosus* woodland, per. Sawyer et al. 2009) covers just over 5 acres adjacent to the solar generator site (see Figure DR70-1 of CH2MHill 2010a). It is characterized by smoke tree (*Psorothamnus spinosus*), although smaller shrubs may have greater cover (Sawyer et al. 2009). In the project area, burrobrush cover is approximately equal to smoke tree cover in this woodland. Blue palo verde (*Cercidium floridum*) is also present in the tree layer and white bursage and creosote bush are present in the shrub layer. The nonnative, invasive annual, Sahara mustard, is common in the herb layer. This community is ranked by CDFG (2003) as a special-status vegetation type, with state rarity ranking of S3. It is one of several communities included within broader vegetation types called desert wash woodland or microphyll woodland (Holland 1986; Schoenherr and Burk 2007). Project construction would not directly affect smoke tree woodland.

Vegetation on the proposed solar generation site has largely recovered from removal or crushing during the site's historic use as an airfield. However, soils throughout much of the project site remain somewhat compacted and remnants of pavement, tar, or oil are evident on the soil surfaces throughout much of the site. Recovering vegetation is visually similar to surrounding undisturbed desert lands, though shrubs tend to be smaller and overall diversity is lower on the former airfield site.

Vegetation on the proposed generator tie-line alignment is also predominantly creosote bush scrub, as described above. The alignment crosses several broad sandy washes where blue palo verde is common, though these areas were not mapped as distinct vegetation types due either to the 5-acre minimum mapping unit or to relatively greater cover of creosote bush (see Figure DR70-1 of CH2MHill 2010a). Staff notes that soils along the proposed generator tie-line alignment are essentially undisturbed, by comparison with the proposed solar generation site. That is, soils on the tie-line alignment were not compacted, paved, or oiled during the 1940s. Thus, native shrublands are generally more diverse and more mature than shrublands on the proposed solar generation site.

Field surveys of the Western Parker-Blythe #2 transmission line have not been provided for staff's review. Staff reviewed aerial images of the transmission line alignment on Google Earth and found that the majority of the alignment appears to cross creosote bush shrubland. In addition, portions of the existing alignment appear to cross riparian,

microphyll woodland, and sand dune habitats. Washes and streambeds occur intermittently along the length of the alignment, and appear to vary from intermittent dry washes to perennial riparian areas. The most prominent of these washes are in two general locations described below.

The first is located near the northern end of the alignment, at the Parker Dam Substation and continues to just south of U.S. Highway 95 (34°06'10"N 114°30'31"W). This area contains many washes, including Eureka Wash (34°17'29"N 114°09'03"W) and Copper Basin Wash (34°15'16"N 114°12'19"W), which both appear to support riparian vegetation. The second general area that appears to support riparian vegetation is south of the Big Maria Mountains southward to the area south of the McCoy Wash (33°51'41"N 114°42'08"W to 33°40'05"N 114°41'01"W). The McCoy Wash appears to support riparian vegetation and there are numerous additional sandy washes throughout this area which could contain additional riparian habitat.

One area along the Western Parker-Blythe #2 transmission line appears to contain sand dune habitat that could provide suitable habitat for Mojave fringe-toed lizard (described below). This area is part of a larger sand dune area north of the Big Maria Mountains (33°57'02"N, 114°40'15"W).

The following descriptions of desert wash and desert dune vegetation are based on a review of published works, but not on site-specific field work on the 161-kV transmission line alignment. Desert riparian vegetation is found along the banks of the Colorado River and some of its tributaries. Where surface or shallow subsurface water is available, these sites may support any of several different woodland or shrubland riparian communities. Examples of these include Fremont cottonwood (*Populus fremontii*) or velvet ash (*Fraxinus velutina*) woodlands, and shrubby willow (*Salix* spp.), mulefat (*Baccharis salicifolia*), or arrow-weed (*Pluchea sericea*) stands (Holland and Kiel 1995; Laudenslayer 1988). Where surface water is available only during storms and subsurface water is deeper, washes in the Colorado Desert support shrubby woodlands described as "microphyll woodland," "desert dry wash woodlands," vegetation, (Thorne 1976; Holland 1986; Laudenslayer 1988; Holland and Keil 1995; Schoenherr and Burk 2007). Smoke tree woodland (described above) is one example of a dry wash microphyll woodland. Other typical species include catclaw acacia (*Acacia greggii*), mesquite (*Prosopis* spp.), desert willow (*Chilopsis linearis*), desert ironwood (*Olneya tesota*), indigo bush (*Psoralea* spp.), blue palo verde, and desert-lavender (*Hyptis emoryi*).

The existing 161-kV Parker-Blythe transmission line crosses sand dune habitat in the Rice Valley. Vegetation on desert sand dunes is typically sparse and dominated by scattered shrubs such as creosote bush, mesquite, numerous tap-rooted annual wildflowers, and deep-rooted perennial herbs such as big galleta (*Pleuraphis rigida*), dicoria (*Dicoria canescens*) and dune-mat (*Tiquilia palmeri*).

Wildlife

The project area supports a broad diversity of wildlife species, briefly described in the following paragraphs. Special-status species mentioned here are discussed in greater detail in the sections that follow. Although the heliostat field would be located largely on

an abandoned, previously disturbed airfield, desert scrub vegetation has recolonized the area and there are no barriers to wildlife usage at the site. During a reconnaissance-level field visit, staff noted that the density of small mammal burrows and abundance of scat seemed low compared with surrounding undisturbed desert lands. This may be due to soil compaction or other alterations, or to reduced native shrub diversity on the site (above).

The proposed tie-line and substation locations would be on open, relatively undisturbed desert scrub habitat. Wind-blown sand dune habitats are found south of the proposed solar site, and fine sandy substrates extend into the project footprint via numerous sandy washes. These types of features increase the biodiversity of the site, as some habitat specialist species use these areas exclusively (whereas generalist species occur in more common habitats ranging throughout the region). For example, the Mojave fringe-toed lizard is closely associated with sand dunes, sand sheets, and fine sandy soils, but generally not on nearby alluvial fans and bajadas. The Mojave fringe-toed lizard is known from the Rice Valley (BLM and CDFG 2002), and was detected 0.75 mile from the project site during surveys for the RSEP (SR 2009a).

Some of the reptile species reported on the site include State and federally listed threatened desert tortoise (*Gopherus agassizii*), side-blotched lizard (*Uta stansburiana*), desert iguana (*Dipsosaurus dorsalis*), western whiptail (*Aspidoscelis tigris*), zebra-tailed lizard (*Callisaurus draconoides*), desert horned lizard (*Phrynosoma platyrhinos*), long-nosed leopard lizard (*Gambelia wislizenii*), and sidewinder (*Crotalus cerastes*) (Appendix 5.2C of SR 2009a). Mammals recorded during the surveys include black-tailed jackrabbit (*Lepus californicus*), coyote (*Canis latrans*), and desert kit fox (*Vulpes macrotis*) (Appendix 5.2C of SR 2009a). Burro deer (*Odocoileus hemionus crooki*) or Nelson's bighorn sheep (*Ovis canadensis nelson*) may also move through the area for forage or dispersal. The Yuma mountain lion (*Felis concolor browni*), a California Species of Special Concern and a predator of the burro deer and bighorn sheep, may also move through the project area.

Despite the moderate to low shrub density, the project area provides forage, cover, roosting, and nesting habitat for a variety of bird species. In addition, many species, such as golden eagle and prairie falcon (*Falco mexicanus*), nest in the adjacent mountains and are likely to forage over the project area, but there are no large trees on the solar generator site suitable for large raptor nesting or roosting. Both of these are special status species, addressed in further detail below. These and other raptors also are expected to forage over the site outside the breeding season. Many raptors from more northern latitudes winter in the regional deserts where they forage over very wide areas. Common resident and migratory birds detected in and near the RSEP site in 2009 by the applicant include lesser nighthawk (*Chordeiles acutipennis*), white-winged dove (*Zenaida asiatica*), yellow-headed blackbird (*Xanthocephalus xanthocephalus*), horned lark (*Eremophila alpestris*), black-throated sparrow (*Amphispiza bilineata*), and barn swallow (*Hirundo rustica*). Common raven (*Corvus corax*), brown-headed cowbird (*Molothrus ater*), northern mockingbird (*Mimus polyglottos*), great-tailed grackle (*Quiscalus mexicanus*), western tanager (*Piranga ludoviciana*), and common poorwill (*Phalaenoptilus nuttallii*) were also observed. Raptors and owls detected at the site include red-tailed hawk (*Buteo jamaicensis*), burrowing owl (*Athene cunicularia*), a

special status species), and turkey vulture (*Cathartes aura*) (Appendix 5.2C of SR 2009a).

No field surveys of the Western Parker-Blythe #2 transmission line have been provided for staff's review. Staff believes that the majority of construction-related disturbance along that transmission line for fiber optic OPGW installation would be within creosote bush scrub vegetation, providing wildlife habitat similar to that described above. In addition, however, some segments of the transmission line appear to cross sand dunes and desert washes, including riparian and microphyll woodland habitats. A variety of additional special status plants and animals not addressed below could occur in these habitats. Desert riparian habitat, if present on the alignment, may support breeding habitat for several special status bird species including listed threatened or endangered species (least Bell's vireo or southwestern willow flycatcher). Desert microphyll woodland is a more productive habitat than surrounding uplands and supports breeding desert bird species in higher densities (Laudenslayer 1988). During migration seasons, is important as stopover habitat for large numbers of migratory songbirds. Desert dunes support several specialized species, including the BLM-sensitive Mojave fringe-toed lizard (below).

Special-Status Species

The project area supports a variety of special-status plant and wildlife species. In addition, habitat on the site and generator tie-line appears to be suitable for several additional special-status species. **Biological Resources Table 4** lists all special-status species evaluated during the analysis that occur or could occur in the project area and vicinity. Special-status plant¹ and wildlife² species detected or considered possible or likely to occur based on geographic distribution and habitat suitability within the project area are discussed in more detail below. Special-status species observed on the project site are indicated by bold-face type. Potential for occurrence is defined as follows:

- Present:** Species or sign of their presence observed on the site during surveys conducted for the proposed project (species that are present are noted in **bold text** in **Biological Resources Table 4**).
- High:** Species or sign not observed on the site, but reasonably certain to occur on the site based on conditions, species ranges, and recent records (generally within approximately 20 years and 10 miles of project site, depending on the species' life history).
- Moderate:** Species or sign not observed on the site, but conditions suitable for occurrence, site is within or near known distribution, and/or an historical record (generally greater than 20 years old) exists in the vicinity (generally

¹ Baldwin et al. (2001), California Native Plant Society (CNPS 2010), the Consortium of California Herbaria (2010), California Natural Diversity Database (CDFG 2010a, 2010b); Munz (1974); Turner et al. (1995); Shreve and Wiggins (1964)

² Occurrence probability based on literature reports, including: Barbour & Davis 1969; Bolster 1998; CDFG 2009, 2010a; Feldhamer et al. 2003; Garrett & Dunn 1981; Grinnell & Miller 1944; Grismer 2002; Hall 1981; Ingles 1965; Jennings and Hayes 1994; National Geographic Society 2002; Shurford & Gardili 2008; Small 1994; Stebbins 2003; Williams 1976; US Fish and Wildlife Service 2009; Wilson & Ruff 1999; Zeiner et al. 1988-1990.

within approximately 10 miles of project site, depending on the species' life history).

Low: Species or sign not observed on the site, and conditions marginal for occurrence.

Not Likely to Occur: Species or sign not observed on the site, outside of the known geographic and/or elevational range, and conditions unsuitable for occurrence.

Biological Resources Table 4
Special-Status Species, Their Status, and Potential Occurrence
at the Rice Solar Energy Solar Generator, Generator Tie-Line, and Interconnector
Substation Project Site

Scientific Name	Common Name	Status	Potential For Occurrence On-Site
PLANTS			
<i>Abronia villosa</i> var. <i>aurita</i>	Chaparral sand verbena	CNPS 1B.1 BLM S S 2.1	Present. Two individuals were observed within the solar generation site in 2009 (Appendix 5.2B of SR 2009a).
<i>Acleisanthes longiflora</i>	Angel trumpets	CNPS 2.3 S 1.3	Not Likely to Occur. Apparently limited to carbonate outcrops; no suitable habitat on plant site or transmission line.
<i>Ammoselinum giganteum</i>	Desert sand parsley	CNPS 2.3 SH	Low. Not found during field surveys; no suitable soils. Occurs in heavy soils of desert basins; only historic Calif. occurrences near Hayfield.
<i>Androstephium breviflorum</i>	Pink funnel-lily, Small-flowered androstephium	CNPS 2.2 S 1.2	Low potential in washes or sandy sites of transmission line corridor; Not Likely to Occur on plant site; occurs in aeolian sand.
<i>Astragalus insularis</i> var. <i>harwoodii</i>	Harwood's milk-vetch	CNPS 2.2 S 2.2?	Present. A total of 30-40 individuals were observed at 5 separate locations along the transmission line corridor in 2009 (Appendix 5.2B of SR 2009a).
<i>Astragalus lentiginosus</i> var. <i>borreganus</i>	Borrego milk-vetch	CNPS: 4.3 S 3.3	Low potential in washes or sandy sites of transmission line corridor; Not Likely to Occur on plant site; occurs in aeolian sand.
<i>Astragalus lentiginosus</i> var. <i>coachellae</i>	Coachella Valley milk-vetch	FE CNPS 1B.2 BLM S S 2.1	Not Likely to Occur. No suitable aeolian soils on plant site; marginally suitable soils on transmission line; all known occurrences well to west.
<i>Astragalus tricarinatus</i>	Triple-ribbed milk-vetch	FE CNPS 1B.2 BLM S S 2.1	Not Likely to Occur. All known occurrences well to west in canyons and washes of eastern San Bernardino, Little San Bernardino, and San Jacinto mtns.
<i>Ayenia compacta</i>	California ayenia	CNPS 2.3 S 3.3	Not Likely to Occur. All known occurrences well to west; generally occurs in rocky canyons; no such habitat on project site.
<i>Bouteloua trifida</i>	Three-awned grass	CNPS 2.3 S 2?	Low. Spring-blooming annual, generally occurs rocky foothills; habitat on-site is marginally suitable; not seen during field surveys.

Scientific Name	Common Name	Status	Potential For Occurrence On-Site
<i>Calliandra eriophylla</i>	Pink fairy duster	CNPS 2.3 S 2.3	Low. Conspicuous perennial species, flowers during late winter or early spring; not seen during field surveys.
<i>Camissonia arenaria</i>	Sand evening-primrose	CNPS 2.2 S 2	Low. All known occurrences well to south; not located during field surveys.
<i>Cassia</i> – see <i>Senna</i>			
<i>Castela emoryi</i>	Emory's crucifixion thorn	CNPS: 2.3 S 2.2	Low. Conspicuous shrub, gen. occurring in washes or playas; habitat marginal on plant site; suitable on transmission line route; not seen during field surveys.
<i>Chamaesyce abramsiana</i> (<i>Euphorbia abramsiana</i>)	Abram's spurge	CNPS 2.2 S 1.2	Low potential in washes or sandy sites of transmission line corridor; Not Likely to Occur on plant site; occurs in aeolian sand.
<i>Chamaesyce arizonica</i> (<i>Euphorbia arizonica</i>)	Arizona spurge	CNPS 2.3 S 1.3	Low potential in washes or sandy sites of transmission line corridor; Not Likely to Occur on plant site; occurs in aeolian sand. Not seen during field surveys.
<i>Chamaesyce platysperma</i> (<i>Euphorbia platysperma</i>)	Flat-seeded spurge	CNPS 1B.2 BLM S S 1.2?	Low potential in washes or sandy sites of transmission line corridor; Not Likely to Occur on plant site; occurs in aeolian sand. Not seen during field surveys.
<i>Colubrina californica</i>	Las Animas colubrina	CNPS 2.3 S2S2.3	Low. Conspicuous shrub, not located during field surveys.
<i>Condalia globosa</i> var. <i>pubescens</i>	Spiny abrojo	CNPS 4.2 S 3.2	Low. Conspicuous shrub, not located during field surveys.
<i>Coryphantha alversonii</i> (<i>Escobaria vivipara</i> var. <i>alversonii</i>)	Foxtail cactus	CNPS: 4.3 S 3.2	Low. Generally on rocky foothills sites; habitat on-site is marginal; not located during field surveys.
<i>Cryptantha costata</i>	Ribbed cryptantha	CNPS: 4.3 S 3.3	Low potential in washes or sandy sites of transmission line corridor; Not Likely to Occur on plant site; occurs in aeolian sand. Not seen during field surveys.
<i>Cryptantha holoptera</i>	Winged cryptantha	CNPS: 4.3 S 3?	Low. Potential habitat is present, but not located during field surveys.
<i>Cylindropuntia wigginsii</i> (<i>Opuntia wigginsii</i>)	Wiggins' cholla	CNPS 3.3 S 1.2?	Not Likely to Occur. Small form of the common silver cholla; current understanding among specialists is that recognition of this form as a distinct species or subspecies is "untenable."
<i>Cynanchum utahense</i>	Utah cynanchum, Utah vine milkweed	CNPS: 4.2 S 3.2	Moderate. Reported in desert tortoise survey, perhaps from tortoise zone of influence transects; not reported on-site by botanical survey; suitable habitat present.
<i>Ditaxis claryana</i>	Glandular ditaxis	CNPS: 2.2 S1S2	Moderate on transmission line route, low on solar generation site. Perennial herb, seasonality varies; not seen during field surveys.
<i>Ditaxis serrata</i> var. <i>californica</i>	California ditaxis	CNPS: 3.2 S 2.2	Moderate on transmission line route, low on solar generation site. Perennial herb, seasonality varies; not seen during field surveys.
<i>Eriastrum harwoodii</i>	Harwood's phlox	CNPS: 1B.2 BLM S S 2	Not Likely to Occur. Occurs on aeolian dunes. Not located during field surveys.

Scientific Name	Common Name	Status	Potential For Occurrence On-Site
<i>Escobaria</i> – see <i>Coryphantha</i>			
<i>Euphorbia</i> – see <i>Chamaesyce</i>			
<i>Gilia</i> – see <i>Linanthus</i>			
<i>Horsfordia alata</i>	Pink velvet mallow	CNPS: 4.3 S 3.3	Low. Occurs in canyons and washes; suitable habitat present but not located during field surveys.
<i>Hymenoxys odorata</i>	Bitter hymenoxys	CNPS 2 S 2	Not Likely to Occur. Occurs in desert riparian shrubland and adjacent desert scrub. All known occurrences closely associated with Colorado River.
<i>Imperata brevifolia</i>	California satintail	CNPS 2.1 S 2.1	Not Likely to Occur. Occurs in desert riparian or seep habitats; no suitable habitat on-site.
<i>Linanthus maculatus</i>	Little San Bernardino Mountains linanthus	CNPS: 1B.2 BLM S	Not Likely to Occur. All known occurrences well to west; generally occurs in fine-sandy alluvial benches; little or no such habitat on project site.
<i>Matelea parvifolia</i>	Spearleaf	CNPS: 2.3 S 2.2	Moderate on transmission line route, low on solar generation site. Perennial herb, seasonality mid-spring.
<i>Mentzelia puberula</i>	Argus blazing star	n/a ³	Not Likely to Occur. Occurs in rocky cliffs and slopes. Not located during field surveys, no suitable habitat on site.
<i>Nemacaulis denudata</i> var. <i>gracilis</i>	Slender woolly-heads	CNPS: 2.2 S2S3	Not Likely to Occur. Occurs on aeolian dunes. Not located during field surveys.
<i>Opuntia</i> – see <i>Cylindropuntia</i>			
<i>Penstemon albomarginatus</i>	White-margined beardtongue	CNPS: 1B.1 BLM S S1	Not Likely to Occur. Occurs on aeolian dunes; all known California occurrences well to north or northwest. Not located during field surveys.
<i>Pholistoma auritum</i> var. <i>arizonicum</i>	Arizona pholistoma	CNPS: 2.3 S 1.3	Low. Occurs in desert shrublands; only known California occurrences are in Whipple Mtns. Flowers early spring; not located during field surveys.
<i>Physalis lobata</i>	Lobed ground-cherry	CNPS: 2.3 S 1.3?	Not Likely to Occur. Occurs on dry lake margins and playas; no suitable habitat on the project site.
<i>Proboscidea althaeifolia</i>	Desert unicorn plant	CNPS 4.3 S 3.3	Low on solar generation site, moderate on transmission line route. Sandy habitats. Spring or summer-flowering perennial herb; not located during early-season field surveys.
<i>Psoralea fremontii</i> var. <i>attenuatus</i>	Narrow-leaved psoralea	CNPS: 2.3 S 2.3	Low. Margin of geographic range; marginal habitat; not located during early-season field surveys.
<i>Salvia greatae</i>	Orocopia sage	CNPS 1B.3 BLM S S 2.2	Low. Desert shrublands on alluvial slopes; known occurrences well to west; not located during field surveys.
<i>Senna covesii</i> (<i>Cassia covesii</i>)	Coves' cassia	CNPS: 2.2 S 2.2	Low on solar generation site, moderate on transmission line route. Spring-flowering perennial herb; not located during early-season field surveys.
<i>Stylocline sonorensis</i>	Mesquite nest straw	CNPS 1A BLM S S X	Not Likely to Occur. Historically occurred at Hayfield Dry Lake; now presumed extirpated in Calif.; no suitable lakebed / playa habitat, no local occurrences.

³ Proposed new addition to the CNPS Inventory (Andre, pers comm.)

Scientific Name	Common Name	Status	Potential For Occurrence On-Site
<i>Teucrium cubense</i> ssp. <i>depressum</i>	Dwarf germander	CNPS: 2.2 S 2	Low. Generally occurs in aeolian sand or desert playas. Habitat on site is marginal. Not located during early-season field surveys.
<i>Teucrium glandulosum</i>	Desert germander	CNPS: 2.3 S 1.3	Low. Occurs in rocky foothill slopes and canyons; only known California occurrences are from Whipple Mtns. Habitat on site is marginal.
<i>Wislizenia refracta</i> ssp. <i>refracta</i>	Jackass-clover	CNPS: 2.2 S 1.2?	Low on solar generation site, moderate on transmission line route. Generally in dunes, playas, desert shrublands. Not located during early-season surveys.
<i>Wislizenia refracta</i> ssp. <i>palmeri</i>	Palmer's jackass clover	n/a ⁴	Low on solar generation site, moderate on transmission line route. Generally in dunes, playas, desert shrublands. Not located during early-season surveys.
INVERTEBRATES			
<i>Oliarces clara</i>	Cheeseweed owlfly (cheeseweed moth lacewing)	BLM S	Present. Reported by CNDDDB immediately adjacent to or within the generator tie-line corridor (CDFG 2010a) based on a 1978 record. Suitable habitat throughout project area.
<i>Eremarionta immaculata</i>	White desert snail	n/a	Not Likely to Occur. Apparently endemic to the Riverside Mountains, approximately 6.2 miles from the proposed solar site and 4 miles from the generator tie-line. No suitable habitat (rocky or talus areas) within project area.

⁴ Proposed new addition to the CNPS Inventory (Silverman, pers comm.)

Scientific Name	Common Name	Status	Potential For Occurrence On-Site
AMPHIBIANS			
<i>Scaphiopus couchi</i>	Couch's spadefoot	BLM S CSSC	Low. Margin of geographic range (BLM and CDFG 2002) and unsuitable habitat. Site drainage, sandy soils, and topography are unlikely to provide sufficiently inundated pools or ditches on-site or in the general area to support breeding.
REPTILES			
<i>Gopherus agassizii</i>	Desert tortoise	FT ST	Present. Recorded during protocol surveys of solar site and transmission line route in 2009: 7 tortoises, 91 shell-skeletal remains, 66 burrows, 3 egg shell fragment locations, and 56 scat events were detected (SR 2009a).
<i>Heloderma suspectum cinctum</i>	Banded Gila monster	BLM S CSSC	Low. Site is at margin of geographic range and habitat generally only marginally suitable. Nearest reported occurrence is historic record (1943) in Granite Mountains, approximately 17 miles southwest of RSEP site (CDFG 2010a). More likely to occur in rocky areas in the surrounding mountains.
<i>Lichanura trivirgata</i>	Rosy boa	BLM S	Moderate. Potential marginal habitat occurs onsite, and the NECO distribution map for the rosy boa includes the entire RSEP area and only excludes the dune areas of the Rice Valley. More likely to occur in rocky areas in the surrounding mountains.
<i>Phrynosoma mcallii</i>	Flat-tailed horned lizard	BLM S CSSC	Not Likely to Occur. Outside of the known geographic range; habitat marginal. Outside mapped range (BLM and CDFG 2002).
<i>Sauromalus obesus</i>	Chuckwalla	n/a	Not Likely to Occur. No suitable habitat. Expected in rocky areas of surrounding mountains, but unlikely in the flat, exposed, and sparsely vegetated project site. Project site and transmission line lack appropriate rocky, talus, or scree habitat. Outside mapped range (BLM and CDFG 2002).
<i>Uma notata</i>	Colorado Desert fringe-toed lizard	BLM S CSSC	Not Likely to Occur. Project area outside of known geographic range. Fringe-toed lizards in Rice Valley are the similar Mojave fringe-toed lizard (below). Outside mapped range (BLM and CDFG 2002).
<i>Uma scoparia</i>	Mojave fringe-toed lizard	BLM S CSSC	High. Observed during the 2009 tortoise survey in dune habitat approximately 0.75 miles south of the site boundary, but not on the site or proposed transmission line alignment. Habitat on the proposed solar generation site is marginal; more suitable sandy washes are found on the proposed transmission line alignment. Within mapped range (BLM and CDFG 2002).
BIRDS			
<i>Accipiter cooperii</i>	Cooper's hawk	CDFG WL (nesting)	High (winter only). No breeding habitat and well outside breeding range; wide-ranging during winter, likely to forage on-site during winter or migratory seasons.

Scientific Name	Common Name	Status	Potential For Occurrence On-Site
<i>Accipiter striatus</i>	Sharp-shinned hawk	CSSC (nesting)	High (winter only). No breeding habitat and well outside breeding range; wide-ranging during winter, likely to forage on-site during winter or migratory seasons.
<i>Aquila chrysaetos</i>	Golden eagle	BLM S FBCC SP CDFG WL	High (foraging only). There is known nesting habitat in the nearby mountains; suitable foraging habitat occurs throughout project site and transmission line alignment. Within mapped range (BLM and CDFG 2002). Protected under Federal Bald and Golden Eagle Protection Act.
<i>Asio otus</i>	Long-eared owl	CSSC (nesting)	Not Likely to Occur. Requires large trees for nesting, and forages in surrounding area, mainly meadows, grasslands, and agricultural lands. No suitable breeding habitat on-site or in nearby area.
<i>Athene cunicularia</i>	Western burrowing owl	BLM S FBCC CSSC	Present. Active burrows observed in project area during 2009 and 2010 (SR 2009a; CH2Mhill 2010e). Within mapped range (BLM and CDFG 2002).
<i>Buteo regalis</i>	Ferruginous hawk	BLM S FBCC CDFG WL	High (winter only). Suitable winter foraging habitat throughout site. Expected during migratory and winter seasons. Within mapped range (BLM and CDFG 2002).
<i>Circus cyaneus</i>	Northern harrier	CSSC (nesting)	Moderate (winter only). Outside breeding range and no suitable breeding habitat occurs in the region; there is potential for infrequent winter foraging throughout desert regions.
<i>Colaptes chrysoides</i>	Gilded flicker	FBCC SE	Not Likely to Occur. No suitable nesting habitat (saguaro cacti or large trees that would provide appropriate cavity nests).

Scientific Name	Common Name	Status	Potential For Occurrence On-Site
<i>Falco columbarius</i>	Merlin	CDFG WL	High (winter only). Outside breeding range; potential foraging habitat throughout site during winter or migratory seasons.
<i>Falco mexicanus</i>	Prairie falcon	FBCC CDFG WL (nesting)	Present (foraging). Observed during April/May 2009 (SR 2009a). Nest sites are reported from the mountains surrounding Rice Valley (CDFG 2010a); suitable foraging habitat throughout the project site. Within mapped range (BLM and CDFG 2002).
<i>Lanius ludovicianus</i>	Loggerhead shrike	FBCC CSSC (nesting)	Present. Observed in project area during 2009 tortoise surveys. Likely nests in shrubs on proposed solar site and within generator tie-line corridor. Suitable habitat throughout the project site.
<i>Melanerpes uropygialis</i>	Gila woodpecker	FBCC SE	Not Likely to Occur. No suitable nesting habitat (saguaro cacti or large trees that would provide appropriate cavity nests). Habitat is identified immediately south of the proposed generator tie-line interconnection point (BLM and CDFG 2002).
<i>Polioptila melanura</i>	Black-tailed gnatcatcher	n/a	High. Suitable habitat in shrublands, especially around washes. Former species of concern. Common and populations apparently now stable.
<i>Toxostoma bendirei</i>	Bendire's thrasher	BLM S FBCC CSSC	Not Likely to Occur. Marginal habitat and outside known breeding range. Generally occurs with Joshua trees or other <i>Yucca</i> species, or high abundance of cholla cacti. Reported in 1920 approx. 4 miles north of the solar field site (CDFG 2010a). Outside mapped range (BLM and CDFG 2002).
<i>Toxostoma crissale</i>	Crissal thrasher	FBCC CSSC	High (transmission line only). Occurs throughout region in dense, scrubby desert wash habitats; suitable habitat occurs periodically along proposed transmission line alignment, but habitat on proposed solar facility generally poorly suitable due to open structure; only low occurrence probability on-site. Outside mapped range (BLM and CDFG 2002).
<i>Toxostoma lecontei</i>	LeConte's thrasher	BLM S FBCC CDFG WL	High. Reported in 1920 approx. 2 miles northwest of the solar field site (CDFG 2010a). Suitable habitat present throughout the project area. Desert populations are apparently stable; CDFG special concern ranking applies only to San Joaquin Valley population (Shuford and Gardali 2008). Within mapped range (BLM and CDFG 2002).
MAMMALS			
<i>Antrozous pallidus</i>	Pallid bat	BLM S CSSC	Moderate (foraging). Roosts in rock outcrops of shrublands; potential roosting in nearby mountains (offsite) and foraging through the Rice Valley. Within mapped range (BLM and CDFG 2002).
<i>Corynorhinus townsendii</i>	Townsend's big-eared bat	BLM S CSSC	Moderate (foraging). Roosts primarily in caves, tunnels, mines; feeds mainly on moths; may roost in nearby mountains and forage through the Rice Valley but activity is more likely concentrated along the Colorado River Valley (SR 2009a). Within mapped range (BLM and CDFG 2002).

Scientific Name	Common Name	Status	Potential For Occurrence On-Site
<i>Euderma maculatum</i>	Spotted bat	BLM S CSSC	Low. Occurs in deserts during winter, but roosts in deep crevices in cliffs and feeds on moths captured over open water; project site lacks major habitat elements.
<i>Eumops perotis californicus</i>	Western mastiff bat	BLM S CSSC	Moderate (foraging). Roosts in deep rock crevices and forages over wide area; may roost in nearby mountains and forage through the Rice Valley. RSEP site out of range but habitat is mapped immediately south of proposed generator tie-line interconnection point (BLM and CDFG 2002).
<i>Felis concolor browni</i>	Yuma mountain lion	CSSC	High. Uncommon; occurs in Colorado Desert, Joshua Tree National Park to Colorado River. Primarily found in dense riparian habitats of Colorado River, and dense microphyll washes in mountainous areas, where water, shaded cover and prey are available. If present, project area likely used primarily for movement. Range includes southern half of the proposed generator tie-line corridor (BLM and CDFG 2002).
<i>Lasiurus xanthinaus (Nycteris ega xanthina)</i>	Western (southern) yellow bat	CSSC	Low. Occurs from Central America, north to southern Arizona; Riverside, Imperial, and San Diego Counties. Riparian and wash habitats; roosts in trees; evidently migrates from California during winter. No suitable roosting habitat on site.
<i>Macrotus californicus</i>	California leaf-nosed bat	BLM S CSSC	Moderate (foraging only). Roosts in mines or caves; expected in surrounding mountains and likely forage occasionally over the proposed project area. Within mapped range (BLM and CDFG 2002).
<i>Myotis occultus</i>	Occult little brown bat, Arizona myotis	CSSC	Low (foraging). Western North America, British Columbia to central Mexico; in the US, mostly occurs in the Pacific states. Roosts in buildings, bridges, caves, mines; feeds over open water. No suitable roosting or foraging habitat on site. The southern end of the proposed generator tie-line corridor is within the mapped range (BLM and CDFG 2002).
<i>Myotis thysanodes</i>	Fringed myotis	BLM S	Low (foraging). Occurs in the four-corners states west to California and the Pacific Northwest, and south through Mexico. Occurs in arid forests & woodlands, roosts in caves, mines, buildings, rock crevices. Scarce in low desert, though may occur along Colorado River where suitable roosting and foraging habitat exists. Range also includes Turtle Mountains north of RSEP and area immediately south of proposed generator tie-line interconnection point (BLM and CDFG 2002).
<i>Myotis velifer</i>	Cave myotis	BLM S CSSC	Low (foraging). Occurs in Mexico through Arizona to the Colorado River area, also southeast US. In California, largely restricted to the desert along the Colorado River. Generally roosts in caves; typically feeds over water or riparian vegetation. Known from the Riverside Mountains. The southern end of the proposed generator tie-line corridor is within the mapped range (BLM and CDFG 2002).

Scientific Name	Common Name	Status	Potential For Occurrence On-Site
<i>Myotis yumanensis</i>	Yuma myotis	BLM S CSSC	Low (foraging). W N. America, British Columbia to cent. Mexico; in the US, mostly the Pacific states; roost in buildings, bridges, caves, mines; feed over open water
<i>Neotoma albigula venustra</i>	Colorado Valley woodrat	n/a	Low. Desert shrubland in southeastern California, southern corner of Nevada; southwest Arizona, adj. Mexico. Closely associated w/ beavertail or mesquite thickets; habitat on site marginal at best; not detected during the April/May 2009 desert tortoise surveys. The southern half of the proposed generator tie-line corridor is within the mapped range (BLM and CDFG 2002).
<i>Nyctinomops femorosaccus (Tadarida femorosaccus)</i>	Pocketed free-tailed bat	CSSC	Moderate (foraging). Occurs in deserts and arid lowlands; eastern Riverside and San Diego Counties, through southwest US, Baja California, mainland Mexico. Roosts mainly in crevices of high cliffs; may roost in nearby mountains and forage through the Rice Valley. Reported habitat immediately south of generator tie-line interconnection point (BLM and CDFG 2002).
<i>Nyctinomops macrotis (Tadarida macrotis)</i>	Big free-tailed bat	CSSC	Moderate (foraging). Occurs in the tropics north to North American deserts and coastal California; many scattered locations. Roosts in crevices of rock cliffs; may roost in nearby mountains and forage through the Rice Valley
<i>Odocoileus hemionus eremicus (= O. h. crooki)</i>	Burro deer, desert mule deer	n/a	High. Uncommon. Large home ranges, including montane and bajada habitat throughout Colorado Desert; mainly in scattered mountain ranges and near dependable water sources. If present, project area likely used primarily for movement.

Scientific Name	Common Name	Status	Potential For Occurrence On-Site
<i>Ovis canadensis nelsoni</i>	Nelson's bighorn sheep	BLM S	High. The Turtle Mountains to the north and the Maria Mountains to the south are likely occupied; the West Riverside and Riverside Mountains to the east and southeast may one day be repopulated. May occasionally forage on-site; movement among mountain ranges is important to regional population viability.
<i>Taxidea taxus</i>	American badger	CSSC	High. Uncommon; occurs in mountains, deserts, interior valleys where burrowing animals are available as prey and soil permits digging. Known from Vidal, approximately 17 miles northeast. Suitable habitat throughout the project site
<i>Vulpes macrotis arsipus</i>	Desert kit fox	n/a	Present. Detected during April/May 2009 desert tortoise surveys (SR 2009a).

FE	=	Federally listed Endangered
FT	=	Federally listed Threatened
FD	=	Federally Delisted
FC	=	Federal Candidate
FBCC	=	Federal Bird of Conservation Concern
BLM S	=	BLM Sensitive
SE	=	State listed Endangered
ST	=	State listed Threatened (wildlife)
SR	=	State listed Rare (plants)
CSSC	=	California Species of Special Concern (wildlife)
SP	=	State Fully Protected Species
CDFG WL	=	California Department of Fish and Game Watch List
n/a	=	None of above

CNPS (California Native Plant Society) Designations:

- List 1A = Plants presumed extinct in California
- List 1B = Plants considered by CNPS to be rare, threatened, or endangered in California, and throughout their range
- List 2 = Plants rare, threatened, or endangered in California, but more common elsewhere in their range
- List 3 = Plants about which we need more information – a review list.
- List 4 = Plants of limited distribution – a watch list

CNPS Threat Rank:

- .1 = Seriously endangered in California (over 80% of occurrences threatened/high degree and immediacy of threat)
- .2 = Fairly endangered in California (20-80% occurrences threatened)
- .3 = Not very endangered in California (<20% of occurrences threatened or no current threats known)

CDFG Natural Diversity Database Designations (Applied to special-status plants and sensitive plant communities; where correct category is uncertain, CDFG uses two categories or question marks):

- S1 = Fewer than 6 occurrences or fewer than 1000 individuals or less than 2000 acres
- S1.1 = Very threatened
- S1.2 = Threatened
- S1.3 = No current threats known
- S2 = 6-20 occurrences or 1000-3000 individuals or 2000-10,000 acres (decimal suffixes same as above)
- S3 = 21-100 occurrences or 3000-10,000 individuals or 10,000-50,000 acres (decimal suffixes same as above)
- S4 = Apparently secure in California; this rank is clearly lower than S3 but factors exist to cause some concern, i.e., there is some threat or somewhat narrow habitat. No threat rank.
- S5 = Demonstrably secure or ineradicable in California. No threat rank.
- SH = All California occurrences historical (i.e., no records in > 20 years).

Special-Status Plants

Four special-status plant species are reported on the proposed solar generator site and generator tie-line alignment (SR 2009a; **Biological Resources Figures 2A, 2B**). Two of these species were located during botanical surveys conducted on the proposed solar generation site and transmission line alignment during March 2009 (Appendix 5.2B of SR 2009a); two others were reported in the desert tortoise survey report (Appendix 5.2C of SR 2009a). Staff notes that the seasonal and irregular nature of most plants' life histories and the scheduling of the field surveys provided in the AFC limit staff's ability to interpret the data as submitted for some later-flowering species. There is

a low to moderate probability that additional special-status plants may be discovered within the project area during late-season surveys, described in staff's recommended Condition of Certification **BIO-12** (Special-Status Plant Impact Avoidance and Minimization). **BIO-12** also describes avoidance or compensation measures to mitigate any impacts to those plants.

There have been no botanical surveys or habitat evaluation for special status plants on Western's existing 161 kV transmission line alignment, where new OPGW would be constructed. Potential occurrence or project impacts to special status plants along the length of that transmission line are not described in the SA/DEIS.

Chaparral Sand-Verbena (Abronia villosa var. aurita)

Chaparral sand-verbena is on CNPS List 1B.1. It is described in the literature as an annual herb, but A.C. Sanders (Herbarium, Dept. of Botany and Plant Science, University of California Riverside; pers. comm.) notes that it is perennial and that this is one of the important differences between this and the common desert sand-verbena (*Abronia villosa* var. *villosa*). Chaparral sand-verbena is found in sandy valley floors and alluvial benches in chaparral, coastal scrub, montane transition shrublands, or woodlands. It also is reported from dunes and washes throughout the Colorado Desert (CDFG 2010a; Consortium of California Herbaria 2010) but Sanders (pers. comm.) states that all purported specimens he has seen that were collected in the desert were misidentified. It is found at elevations ranging from about sea level (near the coast) and 5,250 feet elevation (in the San Jacinto Mountains). It blooms between January and September (CNPS 2010). Like most desert species, its above-ground growth and flowering season vary from year to year, depending on the amount and timing of seasonal rainfall. In California it is reported from Imperial, Los Angeles, Orange, Riverside, San Bernardino, San Diego, and Ventura Counties. It also is reported from Arizona and Baja California (CNPS 2010). However, many of these reported locations are from the deserts and may represent misidentified specimens.

There are no CNDDDB records of chaparral sand-verbena on the Rice, Grommet, or Big Maria Mountains northwest quads (CDFG 2010a). The nearest CNDDDB record is based on a specimen collected in 1910, approximately 8.5 mi east of the project site, on the Vidal quad.

Chaparral sand-verbena's distribution and identification are unclear in published reference works, including Spellenberg (1993; 2002), CNPS (2010) and CNDDDB (CDFG 2010a). This plant was added to the CNPS Inventory based on recommendations by Andrew C. Sanders of the UC Riverside Herbarium. The primary conservation concern is for chaparral sand-verbena occurrences in western Riverside County and other locations outside the desert (see Roberts et al. 2004). These western plants appear to be distinct from the very common desert sand verbena, *Abronia villosa* var. *villosa*. The western plants are perennial; their flower tubes are longer; and their fruits are distinctly and broadly winged. All three features can be problematic in specimen identification. The perennial habit is rarely noted on herbarium labels and is not mentioned in Spellenberg (1993; 2002) or Murdock (2010). The flower tube lengths and the winged fruit characters vary widely throughout the range of *A. villosa*. While the western populations have longer tubes and broader wings, these overlap somewhat with desert

plants, especially around Whitewater Canyon in Riverside County. Plants in the Mojave Desert have ridges, but not wings, on the fruits. Plants in the low desert, which would include the RSEP site, often have relatively broad wings on their fruits, though not as broad as the western plants.

The chaparral sand-verbena plants reported on and near the RSEP site in the Botanical Inventory Report included in the AFC (Appendix 5.2B of SR 2009a) were identified by their winged fruits. Staff agrees that this determination is consistent with available published information. However, due to the plant's local distribution and abundance in the Colorado Desert, well outside the area where chaparral sand-verbena is considered rare, staff concludes that this plant is not regionally rare.

Harwood's Milk-Vetch (Astragalus insularis var. harwoodii)

Harwood's milk-vetch is on CNPS List 2.2. It is a perennial herb found in desert dunes and sandy or gravelly desert scrub from about sea level to 2,300 feet elevation. It flowers between January and May (CNPS 2010). Like most desert species, its above-ground growth and flowering season vary from year to year, depending on the amount and timing of seasonal rainfall. In California, Harwood's milk-vetch is known from Imperial, Riverside, and San Diego counties (CNPS 2010). It also occurs in Arizona and Mexico (CNPS 2010). There are no CNDDDB records for Harwood's milk-vetch from the Rice, Grommet, Big Maria Mountains northwest, or the 12 surrounding quads (CDFG 2010a). The closest CNDDDB record is approximately 25 miles south of the project site, on the Ripley quad.

Harwood's milk-vetch was observed at 5 locations along the proposed transmission line alignment corridor (Appendix 5.2B of SR 2009a). A total of 30 to 40 individual plants were observed along the alignment and three additional plants were observed north of and outside the proposed alignment corridor. They were growing in loose sandy/gravelly soils in small desert wash features. Harwood's milk-vetch was not observed within the proposed solar field site.

Utah Cynanchum (Cynanchum utahense)

Utah cynanchum (also called Utah vine milkweed) is on CNPS List 4. It was reported in the species list accompanying the applicant's Desert Tortoise Survey Report, but was not recorded on the site in the Botanical Inventory Report (Appendices 5.2B and 5.2C of SR 2009a). The applicant's response to Data Request No. 73 addresses this discrepancy (CH2MHill 2010a). Apparently, Utah cynanchum was located by desert tortoise biologists outside the proposed project site (e.g., on zone of influence tortoise transects) or was misreported in the desert tortoise survey report, perhaps based on a misidentification of trailing townula (*Sarcostemma hirtellum*, also called rambling milkvine). These two species are similar in that their stems closely resemble one another, although the flower inflorescences are distinct. Sycamore Environmental reexamined photographs and voucher specimens collected during the botanic surveys to determine whether the species previously identified as trailing townula might be Utah cynanchum. This re-analysis confirmed that plants observed on the site by field botanists, and reported as trailing townula in the Botanical Inventory Report, were correctly identified. Utah cynanchum has not been observed or reported on the site by the applicant's botanical consultant. However, the site is within its geographic range

(Bell 2009), and marginally suitable desert wash habitat may be present in desert washes, either on the proposed solar generation site or, more likely, the proposed generator tie-line alignment. Pending the results of ongoing follow-up botanical surveys, staff concludes that Utah cynanchum is not likely to occur on the solar generation site but is moderately likely to occur on the tie-line alignment.

Wiggins' Cholla (Opuntia wigginsii)

Wiggins' cholla is on CNPS List 3 (i.e., the review list of plants for which more information is needed). It was reported in the species list accompanying the applicant's Desert Tortoise Survey Report, but was not recorded on the site in the Botanical Inventory Report (Appendices 5.2B and 5.2C of SR 2009a). The applicant's response to Data Request No. 73 addresses this discrepancy (CH2MHill 2010a). Wiggins' cholla is not recognized by current or recent specialists, including Parfitt and Baker (1993, 2002), Pinkava (2003), and Baker et al. (2010). It is a small form of the common silver cholla (*Opuntia echinocarpa*, or *Cylindropuntia echinocarpa*). Wiggins' cholla has variously been recognized as a distinct species; a hybrid of silver cholla and pencil cholla, or an indistinct small variant of silver cholla. Current understanding among cactus specialists is that recognition of this form as a distinct species or subspecies is "untenable" Pinkava (2003).

During site visits in March and April 2010, staff noted small silver cholla plants occasionally throughout the project site. These may be the plants noted by desert tortoise biologists (above). Staff speculates that their small stature may be due to their young age, because they must have colonized the site since abandonment of the former Rice Army Airfield.

SPECIAL STATUS WILDLIFE

Text provided below evaluates potential occurrence of special status wildlife species on the proposed solar generator site and the associated generator tie-line alignment and substation. See **Biological Resources Figures 3A** and **3B**. No field surveys of the Western Parker-Blythe #2 transmission line have been provided for staff's review. Staff believes that the majority of construction-related disturbance along that transmission line for fiber optic OPGW installation would be within creosote bush scrub vegetation, which would likely provide additional suitable habitat for all special status species described below. The transmission line also crosses sand dunes and numerous washes, though vegetation and habitat at those crossings have not been described or evaluated for their suitability as special status species habitat. Staff believes that a variety of special status dune and riparian species could occur along the alignment, but lacks baseline data to evaluate occurrence or potential project impacts to those species.

Special-Status Invertebrates

Cheeseweed owlfly (Oliarces clara)

Cheeseweed owlfly (also called cheeseweed moth lacewing) has been reported from the proposed generator tie-line corridor (CDFG 2010a). Cheeseweed owflies occur on desert bajadas and canyons where creosote bush is present. Their larvae burrow into the ground and apparently feed on creosote bush roots for "probably upwards of one year" (Faulkner 1990; Arizona Game and Fish Dept. 2003). After metamorphosis, the

adult forms emerge from the soil during April or May. In some years, they may be locally abundant. The adult owlflies do not feed and die within only a few days. Documentation of their presence occurs only during this active flight period. During mating, the males and females aggregate at local high topographic features; this “hilltopping” behavior is common among many insects. After mating, the females lay eggs in sand downslope from the hilltop site. Specific soil requirements for suitable oviposition, if any, are unknown (Arizona Game and Fish Dept. 2003). Johnson (1992) reported that it is much more widespread and abundant than previously believed.

Creosote bush shrubland occurs throughout the RSEP and generator tie-line alignment. However, soil surfaces on much of the site have been hardened by paving or oiling, or compacted by vehicle use. In addition, the proposed solar generation site is several miles distant from suitable hilltop mating sites. The effects of soil hardening or compaction and distance from mating sites to cheeseweed owlfly habitat suitability are not known. The project area does not appear to provide specialized habitat or other resources for cheeseweed owlfly other than those resources widely available throughout the region. Staff believes that similar potentially suitable habitat would be found along the length of Western’s existing 161-kV Parker-Blythe transmission line.

Special-Status Amphibians

Couch’s spadefoot (Scaphiopus couchii)

Couch’s spadefoot, like other spadefoot species, is an amphibian with appearance and life history characteristics similar to the true toads (*Bufo* spp.) but distinguished from that genus by several characteristics, especially the thickened sharp-edged “spades” on the hind feet, used for burrowing (Stebbins 2003). Couch’s spadefoot is almost entirely terrestrial. It is dormant in burrows 20 to 90 cm deep for 8 to 10 months of the year (Jennings and Hayes 1994). It is active on the surface only during periods following warm summer rains, when it emerges to feed on insects and to reproduce. Successful reproduction requires warm rain pools which must hold water while the eggs hatch and the tadpoles develop, and then metamorphose into juvenile spadefoots. This has been reported to occur in as few as 7 to 10 days (Jennings and Hayes 1994; Grismer 2002).

In addition to summer rain pools, Couch’s spadefoot requires soft, sandy soils for burrowing and generally is found at the edges of arroyos or in open soil around the bases of shrubs (Grismer 2002). Adult spadefoots make seasonal movements to and from breeding pools, but movement distances are unknown for this and other spadefoot species (Morey 2005). Some true toads may move as far as 1.2 km between breeding habitat and their upland burrows (Holland and Sisk 2000).

Couch’s spadefoot is widespread in southwestern North America and Mexico. The Colorado Desert in California is at the western margin of its geographic range. Stebbins (2003) indicates that it is restricted in California to a corridor immediately adjacent to the Colorado River, though Morey (2005) indicates a much broader distribution in the California deserts. In California, Couch’s spadefoot is threatened by habitat conversion for other uses. It is ranked as a Species of Special Concern by CDFG and as a Sensitive Species by BLM.

Topography and drainage channel morphology on the proposed solar generation site and along the proposed generator tie-line alignment indicate that no suitable breeding pools would form or hold rain water long enough for spadefoot reproduction (Attachment DR60-1 of CH2MHill 2010a). Upland habitat on the proposed solar generation site may be suitable as winter dormancy/burrowing habitat, depending upon the project site's proximity to breeding pools, the species' movement distances between borrow and breeding sites, and any specific habitat requirements for burrowing sites. Staff believes that potentially suitable habitat would be found along the length of Western's existing 161-kV Parker-Blythe transmission line, particularly where the alignment crosses broad sandy washes.

Special-Status Reptiles

Desert Tortoise (Gopherus agassizii)

The desert tortoise is listed as threatened under the state Endangered Species Act and the Mojave population is listed as threatened under the federal ESA. The federally-listed Mojave population includes those animals living north and west of the Colorado River in the Mojave Desert of California, Nevada, Arizona, and southwestern Utah, and in the Sonoran (Colorado) Desert in California (USFWS 1994a). Outside the listed Mojave population, its range extends into the Sonoran Desert, where tortoises occur in the lower Colorado River Valley, Arizona uplands, plains of Sonora (Mexico), and the central Gulf Coast. The two recognized populations are isolated from one another by the Colorado River. All desert tortoises in California are part of the Mojave population.

Desert tortoises are well adapted to living in a highly variable and often harsh desert environment. They spend much of their lives in burrows, even during their seasons of activity, which generally coincide with the greatest annual forage availability, between March and May. In late winter or early spring, they emerge from over-wintering burrows and typically remain active through fall. During their active periods, desert tortoises eat a wide variety of herbaceous vegetation, particularly grasses and the flowers of annual plants (Berry 1974; Luckenbach 1982; Esque 1994).

Activity decreases in summer, but tortoises often emerge after summer rain storms to drink (Henen et al. 1998). During the summer activity period, tortoises retreat to burrows or shaded "palettes" or other shaded sites beneath shrubs or rocks during the most intense heat, or to rest at night. They may aestivate (summer dormancy) in burrows during extended periods of heat and dryness. A single tortoise may have a dozen or more burrows within its home range, and different tortoises may use these burrows at different times. Adult desert tortoises lose water at such a slow rate that they can survive for more than a year without access to free water of any kind and can apparently tolerate large imbalances in their water and energy budgets (Nagy and Medica 1986; Peterson 1996a, 1996b; Henen et al. 1998). During periods of inactivity, their metabolism and water loss are reduced. Tortoises enter brumation (the reptilian equivalent of hibernation) during autumn (September to November, depending on conditions).

Desert tortoise habitats include desert alluvial fans, washes, canyon bottoms, rocky hillsides, and other steep terrain. Tortoises are most common in desert scrub, desert

wash, and Joshua tree habitats, but occur in almost every desert habitat except on the most precipitous slopes. Friable soils, such as sand and fine gravel, are an important habitat component, particularly for burrow excavation and nesting. The presence of soil suitable for digging burrows is a limiting factor to desert tortoise distribution (USFWS 1994a). Vegetation cover of typical desert tortoise habitat is dominated by creosote bush, burrobush (*Ambrosia dumosa*), Mojave yucca (*Yucca schidigera*), or blackbrush (*Coleogyne ramosissima*). At higher elevations, Joshua trees and galleta grass are common plant indicators (USFWS 1994a).

The size of desert tortoise home ranges varies with respect to location and year (Berry 1986) and also serves as an indicator of resource availability and opportunity for reproduction and social interactions (O'Connor et al. 1994). Female tortoises have long-term home ranges that may be less than half that of the average male's home range, which can range to up to 200 acres (Burge 1977; Berry 1986; Duda et al. 1999; Harless et al. 2009). Core areas used within tortoises' larger home ranges depend on the number of burrows used within those areas (Harless et al. 2009). Over its lifetime, each desert tortoise may use more than 1.5 square miles of habitat and may make periodic forays of more than 7 miles at a time (Berry 1986).

Adult tortoises may reach an overall carapace (shell) length of 9 to 15 inches. Tortoises are long-lived and grow slowly. They require 13 to 20 years to reach sexual maturity. As adults, their reproductive rates are low, though their reproductive lifespan is long (Turner et al. 1984; Bury 1987; Germano 1994). Mating may occur both during spring and fall (Black 1976; Rostal et al. 1994). The number of clutches (set of eggs laid at a single time) and number of eggs that a female desert tortoise produces in a season is dependent on conditions including habitat quality, availability of forage and drinking water, and the animal's physiological condition (Turner et al. 1986, 1987; Henen 1997; McLuckie and Fridell 2002). Egg-laying occurs primarily between April and July (Rostal et al. 1994; USFWS 1994b); the female typically lays 2-14 eggs (average 5-6) eggs in an earthen chamber excavated near the mouth of a burrow or beneath a shrub (Woodbury and Hardy 1948; USFWS 1994b). The eggs typically hatch 90 to 120 days later, between August and October. The success rate of clutches has proven difficult to measure, but predation, while highly variable (Bjurlin and Bissonette 2004), appears to play an important role in clutch failure (Germano 1994).

Desert tortoise populations have declined for several reasons, each of which tends to be exacerbated by the others and most of which are associated with human land uses and other human activities. Most threats identified in the 1980s as the bases for state and federal listing continue to affect tortoise populations today (USFWS 2008a). Habitat degradation and loss due to land use conversion, grazing, mining, energy development, and highway construction and expansion have all contributed to declining numbers and fragmented desert tortoise populations. Off-road vehicle use causes direct mortality from vehicle collision or crushed burrows and destruction of habitat. Desert tortoises are also vulnerable to vehicle collisions on roads and highways. Drought, habitat degradation, and associated weed invasion decrease nutrients available to desert tortoises in their food; this makes them susceptible to upper respiratory tract disease, and possibly other diseases, which can be fatal and is transmittable among populations (Jacobson 1992). Tortoises also are vulnerable to predation by ravens and domestic and feral dogs. Infrastructure development and urbanization creates perch sites and

food and water sources for ravens, and increases numbers of dogs, all of which elevate predation pressure on juvenile tortoises. Other threats include illegal collecting, vandalism, livestock grazing, feral burros, non-native plants, changes to natural fire regimes, and environmental contaminants (USFWS 1994b). Habitat fragmentation and development can isolate tortoise populations, further increasing risk of disease and reducing genetic diversity. This range of threats can kill or indirectly affect desert tortoises and their habitat, but little is known about the relative contribution each threat makes to tortoise demography (Boarman 2002, USFWS 2008a). Current recovery planning (USFWS 2008a) focuses on expanding the knowledge of individual threats and places emphasis on understanding their multiple and combined effects on tortoise populations.

In 1994, tortoise densities in the Eastern Colorado Recovery Unit were estimated between 5 and 175 adult tortoises per square mile and threat level was ranked at 4 out of 5 (5 = extremely high) (USFWS 1994). More recent density estimates are lower (Luckenbach 1982; Berry 1984), though it is unclear whether the lower values reflect actual decline in tortoise numbers, or differences in data collection (USFWS 2006).

The USFWS published the *Desert Tortoise (Mojave Population) Recovery Plan* in 1994 and published a *Draft Revised Recovery Plan for the Mojave Population of the Desert Tortoise* in 2008. Since 1994, research indicates generally continuous variation in genetic structure and ecological biomes across the Mojave population's range. On the basis of this new information, the draft revised recovery plan redefines the recovery units to balance regional distinctiveness and variability within the population. It stresses geographic discontinuities or barriers that coincide with any observed variation among tortoise populations. The draft revised recovery plan reduces the number of recovery units from six to five, to reflect new analyses and ensure that local adaptations and genetic diversity are maintained. These analyses and conclusions are described in the draft revised recovery plan (USFWS 2008a).

The RSEP is located within the Eastern Colorado Recovery Unit (USFWS 1994), which would be merged with the adjacent Northern Colorado Recovery Unit upon finalization of the draft revised recovery plan. The new recovery unit will be referred to as the Colorado Desert Recovery Unit (USFWS 2008). Within this recovery unit desert tortoises are found primarily in "well-developed washes, desert pavements, piedmonts, and rocky slopes characterized by relatively species-rich succulent scrub, creosote bush scrub, and blue palo verde-ironwood-smoke tree communities" (USFWS 1994). Habitat within this recovery unit was described as being in excellent condition despite declines in tortoise densities over the past several decades; disturbance was estimated at less than 1.3 percent throughout (USFWS 2005). The highest desert tortoise densities within this recovery unit are in Chemehuevi and Ward valleys, on the Chuckwalla Bench within the Chuckwalla Desert Wildlife Management Area (DWMA and associated Critical Habitat Unit) and in Joshua Tree National Park. Desert tortoise densities at the Chuckwalla Bench in 1992 were estimated between 22 and 49 adults per square kilometer (approximately 57–127 adults per square mile) but have shown declining trends (Berry 1997; Tracy et al. 2004).

Critical Habitat: The project site is not within designated critical habitat for the desert tortoise. The nearest designated desert tortoise critical habitat is the southeastern

portion of the Chemehuevi Valley Critical Habitat Unit adjacent to SR-62, about five miles east of the site (USFWS 1994a). The Pinto Mountains and Chuckwalla Critical Habitat Units are more distant, to the southwest.

Suitable desert tortoise habitat is present throughout the proposed solar generation site and generator tie-line alignment, and desert tortoises occur within the proposed RSEP footprint and in the adjacent desert areas (Appendix 5.2C of SR 2009a). One tortoise was found in the northwestern portion of the proposed solar generation site; three were found along zone-of-influence (ZOI) transects surrounding the solar field site; and three others were found along the proposed generator tie-line corridor and associated ZOI transects. In addition, a total of 91 shell or skeletal fragments were found during the surveys, indicating desert tortoise occupancy throughout the area in recent years. Three separate observations of eggshell fragments suggest a viable, if low-density population inhabits the project site and surrounding area. Staff believes that similar suitable habitat would be found along the length of Western's existing 161-kV Parker-Blythe #2 transmission line.

Banded Gila Monster (Heloderma suspectum cinctum)

The banded Gila monster is considered rare in California with only 26 credible records documented within the past 153 years (Lovich and Beaman 2007). This large and distinct lizard is difficult to observe even in areas where it has been recently recorded. As a result, little is known about its distribution, population status, and life history in California. Most historical observations in California have been in riparian areas or at moderate elevations of the higher desert mountain ranges, in rocky, incised topography (Lovich and Beaman 2007). In California, the Gila monster may be confined to the eastern deserts (east of 116° longitude) where summer rainfall makes up 25 percent of average annual precipitation (Lovich and Beaman 2007). There has been only one report from farther west (the Mojave River). Throughout its range, the Gila monster appears to be most active during or following summer rains.

The RSEP project site is at the western margin of the banded Gila monster's range, and habitat on the site appears to be only marginally suitable. However, its geographic range is poorly known and it often goes undetected even in occupied habitat. Its occurrence probability on the site is low. Staff believes that potentially suitable habitat may be found along the length of Western's existing 161-kV Parker-Blythe #2 transmission line, particularly where the alignment crosses rocky hills or mountain foothills.

Rosy Boa (Lichanura trivirgata)

The rosy boa occurs in rocky shrublands from sea level to about 6700 feet elevation. In the coastal regions, rosy boas occur south and west of the major mountain chains, in the interior valleys and mountains of Los Angeles, Riverside, San Bernardino, and Orange counties, southward to the coast in San Diego County and Baja California. In the deserts, rosy boas range throughout most of the Mojave Desert and much of the Colorado Desert, eastward into Arizona. They are active during warm seasons, and are primarily nocturnally. The CDFG Natural Diversity Data Base considers rosy boa a "special animal" but it has no formal status under state or federal Endangered Species Acts. It is managed as a Sensitive Species by the BLM.

Habitat on the RSEP site is only marginally suitable for rosy boa due to the relatively flat topography and lack of boulders or rock crevices where they typically take cover. However, the site is within their geographic range and could be occupied at low density. Staff believes that suitable habitat may be found along the length of Western's existing 161-kV Parker-Blythe #2 transmission line, particularly where the alignment crosses rocky slopes and foothills.

Mojave Fringe-Toed Lizard (Uma scoparia)

The Mojave fringe-toed lizard is known almost exclusively from California, primarily in San Bernardino and eastern Riverside Counties, but is also found to the north in southeastern Inyo County and historically to the west in eastern Los Angeles County (Jennings and Hayes 1994). Murphy et al. (2006) identified two genetic lineages of this species. The northern lineage, associated with the Amargosa River drainage system, is under review for federal listing as a threatened or endangered population (USFWS 2008d). The southern lineage is more widespread, ranging through the Mojave River drainage system, Bristol Trough, Clark's Pass (including Palen Lake and Pinto Wash), and the Colorado River sand transport systems (including Rice Valley).

The Mojave fringe-toed lizard is a California Species of Special Concern and BLM Sensitive Species found in arid, sandy, sparsely vegetated habitats and is associated with creosote bush scrub throughout much of its range (Norris 1958; Jennings and Hayes 1994). It is generally restricted to fine, loose, aeolian (windblown) sand habitat, typically with sand grain size no coarser than 0.375 mm in diameter (Turner et al. 1984; Jennings and Hayes 1994; Stebbins 1944). These sands are the most important element of its habitat. It burrows in the sand to avoid predators and to thermoregulate (Stebbins 1944), though it will also seek shelter in rodent burrows. Sand dunes provide its primary habitat, although it can also be found in the margins of dry lakebeds and washes and isolated blow-sand pockets against hillsides (BLM and CDFG 2002).

The Mojave fringe-toed lizard is primarily insectivorous, but also eats leaves, seeds, and buds (Stebbins 1944). It normally hibernates from November to February, and emerges from hibernacula in March or April. The breeding season is April to July, and adult Mojave fringe-toed lizards reach sexual maturity two summers after hatching. Females deposit 2 to 5 eggs in sandy hills or hummocks May through July (Mayhew 1964; Jennings and Hayes 1994). From April to May, while temperatures are relatively cool, it is active during mid-day; from May to September, it is active in mornings and late afternoon, but seeks cover during the hottest parts of the day. Common predators of the Mojave fringe-toed lizard include burrowing owls, leopard lizards, badgers, loggerhead shrikes, roadrunners, various snakes, and coyotes (Jennings and Hayes 1994).

In addition to the aeolian dunes and sandfields where Mojave fringe-toed lizard is best known, it is also found in mixed habitat such as hummocks or pockets of soft sand interspersed with hard-packed sand and less suitable densities and composition of vegetation (Calk and Heaton 2002).

The Mojave fringe-toed lizard is widespread geographically across the Mojave and northern Colorado deserts, but its distribution is highly fragmented because of its

requirement for loose sand, which is patchily distributed (Murphy et al. 2006). Many local populations occur on small patches of sand and consist of relatively few animals. This fragmented distribution leaves local populations vulnerable to extirpation from habitat disturbance, further fragmentation, or stochastic events (Murphy et al. 2006). Aeolian sand habitat is vulnerable to direct and indirect disturbances (Weaver 1981; Beatley 1994; Barrows 1996). Environmental changes that stabilize sand, affect sand sources, or block sand movement corridors will, in turn, affect Mojave fringe-toed lizard habitat and populations (Turner et al. 1984; Jennings and Hayes 1994). Threats include habitat loss or damage from urban and agricultural development, vehicles, and indirect effects such as invasive weeds and increased habitat access by common ravens or other predators. Another important indirect disturbance is the potential disruption of sand source for the dune systems. Dune habitat that is cut off from its sand source will degrade over time as finer sands are blown away, leaving behind smaller dunes composed of coarser-textured sand.

The applicant reported that Mojave fringe-toed lizard is present in the Rice Valley Dunes, within about 0.75 mile of the proposed RSEP site (SR 9009a). The applicant reported no suitable habitat on the proposed solar generation site but noted that Mojave fringe-toed lizards may occur in marginal habitat of sandy washes on the RSEP site. A follow-up habitat assessment (Black 2010) indicated these areas were not conducive to Mojave fringe-toed lizard occupancy. Also, aeolian sand occurs in patches along the proposed generator tie-line alignment (SR 2009a; CH2MHill 2010a; Black 2010). Staff also notes that several sandy desert washes crossing the proposed generator tie-line alignment may provide marginally suitable Mojave fringe-toed lizard habitat. Habitat suitability on the existing 161-kV Parker-Blythe #2 transmission line alignment has not been evaluated, but staff believes that Mojave fringe-toed lizards would be found where the alignment crosses the Rice Valley Dunes and perhaps at other locations along the alignment.

Special-Status Birds

Golden Eagle (Aquila chrysaetos)

Golden eagles are year-round residents throughout most of their range in the western United States. In the southwest, they are more common during winter when eagles that nest in Canada migrate south into the western U.S. They breed from late January through August with peak activity between March and July (Kochert et al. 2002), depending on location. Breeding tends to be earlier in the California deserts than it is farther to the north (Pagel et al. 2010). Migratory patterns are usually fairly local in California where adults are relatively sedentary, but dispersing juveniles sometimes migrate south in the fall. Golden eagles are generally more common in southern California than in the northern part of the state (USFS 2008).

The range of the golden eagle extends throughout the Northern Hemisphere. It is rare in eastern North America and is most common in the west near open spaces that provide foraging opportunities within routine foraging range of cliffs that are used for nesting (Kochert et al. 2002). The golden eagle is a CDFG Fully Protected Species and is a BLM Sensitive Species. Additionally, it is provided federal protection under the Migratory Bird Treaty Act, the Bald and Golden Eagle Protection Act and is listed as a

Bird of Conservation Concern by the USFWS. Threats include habitat loss or damage due to urbanization, agriculture, hunting, pesticide applications, and power line electrocution. The USFWS and others (USFWS 2009a; Kochert et al. 2002) estimate approximately 30,000 golden eagles in the western U.S., down from an estimated 100,000 in the late 1970s. Survey data from 2003 and 2006 to 2008 indicate a decline of 26 percent since 2003. Climate change is expected to impact golden eagle by increasing drought severity; CO₂ concentrations are expected to exacerbate the spread of invasive weeds, which displace native species and habitats, fuel wild fires, and alter fire regimes.

Golden eagle habitat includes rolling foothills, mountain areas, and deserts. Golden eagles need open terrain for hunting and prefer grasslands, deserts, savanna, and early successional forest and shrub habitats. They prey primarily on lagomorphs and rodents but will also take other mammals, birds, reptiles, and some carrion (Kochert et al. 2002). Golden eagles generally nest in rugged, open habitats with canyons and escarpments, with overhanging ledges, cliffs or large trees as cover.

Absent interference from humans, breeding golden eagle density is limited by either prey density or nest site availability (USFWS 2009a). Breeding season home range sizes in the western United States studies showed an average home range of 20 to 33 square kilometers (7.7 to 12.7 square miles). Sizes varied regionally from 1.9 to 83.3 square kilometers (0.7 to 32.2 square miles; Kochert et al. 2002). Other studies have reported much larger upper limits of home range size. In San Diego County, a study of 27 nesting pairs found breeding ranges to be an average of 36 square miles with a range from 19 to 59 square miles (Dixon 1937). Other studies within and outside the United States include ranges from 9 to 74.2 square miles (McGahan 1968; Watson et al. 1992). The USFWS recommends that inventories for golden eagles should be conducted if suitable nesting, roosting, and foraging habitat are present on a proposed project site or within a 10-mile radius of the site (Pagel et al. 2010). Eagles and other raptors forage more widely outside of the nesting season, since they have no need to return daily to eggs or young at their nests.

The project site provides suitable golden eagle foraging habitat but no suitable nesting habitat. There are three golden eagle nesting territories within a 10-mile radius, in the Turtle, Arica, and West Riverside mountains surrounding the site (Bloom 2010). Nests within these territories were not active in May 2010 (Bloom 2010). However, golden eagles in the Colorado Desert may initiate nesting as early as January (Pagel et al. 2010). Thus, these results may be insufficient to conclude that eagles did not nest locally earlier in the year. Also, even if golden eagle territories may be inactive in one year, there is enough documentation available throughout the range of the species to suggest that territories may be vacant for more than a decade, but they may be used later by the same or different individuals as the habitat and prey species cycle through to more productive years. Therefore, unoccupied territories are considered potentially active in future years.

Golden eagles have not been reported over the project site (SR 2009a; CH2MHill 2010e), but the entire RSEP site, including the proposed generator tie-line alignment, provides suitable foraging habitat. Staff notes, however, that foraging habitat on the site has relatively sparse sign of rabbits, jackrabbits, and other small mammals. Previous

land uses or other unknown factors may cause lower productivity on the site than found more widely throughout the region. Staff expects that golden eagles could forage on the site at any time of year. Foraging birds could include mated pairs using the surrounding nesting territories; or, if the territories are inactive, unmated golden eagles or adult birds whose nests may have failed, could forage over the site during breeding season. Foraging would be somewhat more common during winter and migration seasons due to larger numbers of golden eagles in the region and their larger winter foraging ranges. Staff believes that similar suitable foraging habitat would be found along the length of Western's existing 161-kV Parker-Blythe #2 transmission line. The transmission line would be unlikely to cross potential nesting sites due to the rugged topography where they are found. However, parts of the alignment may be within visual range of nest sites.

Western Burrowing Owl (Athene cunicularia)

The burrowing owl is a small, terrestrial owl of open country. Burrowing owls favor flat, open annual or perennial grassland or gentle slopes and sparse shrub or tree cover (Clark and Plumpton 2005). They use the burrows of ground squirrels and other rodents for shelter and nesting (Martin 1973). In California, burrowing owls are found in close association with California ground squirrels (Coulombe 1971). The burrows serve as nesting and refuge sites for the owls, and ground squirrel activity maintains open, low vegetation conditions, which serve as foraging habitat and allow burrowing owls to see potential avian predators (Haug et al. 1993). Habitats lacking ground squirrel populations are usually less suitable for burrowing owls, although the owls can use alternate burrow sites or man-made features (such as drain pipes or debris piles) as burrows in suitable open habitat, even where no ground squirrels are present. Burrowing owls are semi-colonial nesters, and group size contributes significantly to site constancy by breeding burrowing owls (Haug et al. 1993). The nesting season, as recognized by the California Burrowing Owl Consortium (CBOC 1993), is 1 February through 31 August.

In the California deserts, burrowing owls generally occur at low densities in scattered populations, but they can be found in much higher densities near agricultural lands where rodent and insect prey tend to be more abundant (Gervais et al. 2008). Suitable foraging habitat and potential nesting habitat occurs throughout the RSEP project area.

The burrowing owl is as a California Species of Special Concern and is a BLM Sensitive Species. Additionally, it is provided federal protection under the Migratory Bird Treaty Act and is listed as a Bird of Conservation Concern by the USFWS. Threats include habitat loss or damage and a reduction in prey base due to urbanization, mining, trash disposal, pesticide use, grazing activities, off-highway vehicle use, invasion of non-native plants, and brush control activities (BLM et al. 2005).

Burrowing owls occur on the RSEP solar generator site and proposed transmission line alignment. The applicant estimates that as many as seven single burrowing owls or nesting pairs may occur on the project site (five on the solar generator site and another two on the generator tie-line alignment) (CH2MHill 2010h). A total of nine burrows with burrowing owl sign were reported from surveys conducted for the RSEP in 2009 and 2010 (SR 2009a; CH2MHill 2010e). The burrows showed evidence of prior activity but

burrowing owls were not seen during the field surveys. These survey results found no evidence of breeding and suggest that burrowing owls use the RSEP area primarily for wintering, in the months prior to the field surveys. However, it is also possible that they breed there during some years. Staff believes that suitable habitat would be found along the length of Western's existing 161-kV Parker-Blythe #2 transmission line.

Prairie Falcon (*Falco mexicanus*)

Prairie falcons breed throughout most of California, with the exception of the northwest corner of the state and along the immediate coast (Steenhoff 1998). They are uncommon year-around residents, ranging from the southeastern deserts northwest through the Central Valley and along the inner Coast Ranges and Sierra Nevada. Prairie falcons are associated primarily with perennial grasslands, savannahs, rangeland, some agricultural fields, and desert shrublands (Polite and Pratt 2005). Prairie falcon biology is much like that described above for golden eagles, except that birds comprise a much larger proportion of prairie falcon prey (Johnsgard 1990).

The prairie falcon was a CDFG Species of Special Concern, but was removed from this list in 2008 in response to data indicating populations in California are stable or potentially increasing (Shuford and Gardali 2008). The prairie falcon is now on CDFG's watch list. Historic impacts have included eggshell thinning from pesticide residues, conversion of habitat to other uses, robbing of eyries by falconers, and shooting (BLM and CDFG 2002).

A prairie falcon was reported over the site during spring 2009 (Appendix 5.2C of SR 2009a) and prairie falcon nest sites are known from the Arica Mountains and Little Maria Mountains, bordering Rice Valley (CDFG 2010a; Bloom 2010). The date of the observation at the RSEP site suggests that this bird may have been foraging to feed young at a nest somewhere in the region. There is no suitable nesting habitat on the site; however, suitable prairie falcon foraging habitat occurs throughout the project site and surrounding area. Staff believes that similar suitable foraging habitat would be found along the length of Western's existing 161-kV Parker-Blythe #2 transmission line. The transmission line would be unlikely to cross potential nesting sites due to the rugged topography where they are found. However, parts of the alignment may be within visual range of nest sites.

Wintering Raptors

Several migratory raptor species, including Cooper's hawk, sharp-shinned hawk, ferruginous hawk, northern harrier, merlin, golden eagle, and Swainson's hawk spend winters in the southern California deserts or, (for Swainson's hawk) migrate through the region en route to wintering habitat farther south. Outside their breeding seasons, these raptors need not return to their nests to feed young or tend eggs. Thus, they are able to forage over wide areas, where they capture birds or small mammals. Suitable winter or migratory season foraging habitat for all of these raptors is available throughout the project site, and all are expected to forage there on a seasonal basis, though perhaps rarely. Staff believes that similar suitable foraging habitat would be found along the length of Western's existing 161-kV Parker-Blythe #2 transmission line.

Loggerhead Shrike (Lanius ludovicianus)

Loggerhead shrikes are uncommon residents throughout most of the southern portion of their range, including southern California. In southern California they are generally more common in interior desert regions than along the coast (Humple 2008), though breeding bird survey data indicate a significant population decline in the Colorado Desert. In the deserts, they appear to be most numerous in flat or gently sloping bajadas and shrubland margins, especially along the eastern slopes of mountainous areas (Humple 2008). Loggerhead shrikes initiate breeding in February and may continue with raising a second brood as late as July; they often re-nest if their first nest fails or to raise a second brood (Yosef 1996).

Loggerhead shrikes are found in lowland, open habitats where suitable perches are present (e.g., trees or shrubs or, where these are absent, fence posts or other substitutes). Typical habitats include creosote bush or sagebrush shrublands other desert habitats, grasslands, chaparral and riparian area margins, croplands, and areas characterized by open scattered trees and shrubs. In general, loggerhead shrikes prey upon large insects, small birds, amphibians, reptiles, and small rodents, usually impaling prey on thorns, wire barbs, or sharp twigs to cache for later feeding (Yosef 1996).

A loggerhead shrike was observed onsite during the applicant's 2009 desert tortoise surveys (Appendix 5.2C of SR 2009a). Suitable habitat is found throughout the project site and surrounding area. Staff concludes that loggerhead shrike likely nests and forages throughout the site. Staff believes that suitable habitat would be found along the length of Western's existing 161-kV Parker-Blythe #2 transmission line.

Crissal Thrasher (Toxostoma crissale)

Crissal thrasher occurs throughout the Colorado Desert and much of the east Mojave Desert. It typically inhabits dense brush along desert washes, mesquite thickets, and low-desert chaparral. It is often found in desert riparian habitats, such as along the Colorado River, where its habitat is threatened by land use conversion and possibly by invasive species such as tamarisk (Fitton 2008a). It is a CDFG Species of Special Concern. No suitable habitat occurs on the proposed RSEP solar generation site, though the proposed generator tie-line alignment crosses numerous washes which may support Crissal thrashers. It is secretive and patchily distributed in California. It has not been reported on the site or the tie-line alignment but staff concludes that Crissal thrasher could nest and forage on the tie-line alignment. Staff believes that suitable habitat would be found along the length of Western's existing 161-kV Parker-Blythe #2 transmission line.

Le Conte's Thrasher (Toxostoma lecontei)

Le Conte's thrashers inhabit some of the hottest and driest habitats in the arid southwest, including the deserts of southeastern California where it occurs year-round. Its preferred habitats include sparse desert scrub, alkali desert scrub, and desert succulent scrub. Habitats generally are on gentle to rolling slopes associated with dry desert washes, such as found in the project area. Nests are typically placed in prickly vegetation such as cacti or thorny shrubs (Sheppard 1996). Le Conte's thrasher

population densities are among the lowest of passerine (perching) birds, estimated at fewer than five birds per square kilometer in optimal habitats (Fitton 2008b). Due to this low population density, Le Conte's thrashers often are not detected during field surveys, even on sites where they are present. The San Joaquin Valley population is a CDFG Species of Special Concern, though populations elsewhere in the state appear to be stable (Fitton 2008b). Le Conte's thrasher was not reported on the project site (SR 2009a), though suitable habitat is present throughout the site and surrounding area. Staff concludes that it may occur year-round on or adjacent to the project site. Staff believes that suitable habitat would be found along the length of Western's existing 161-kV Parker-Blythe #2 transmission line.

Black-Tailed Gnatcatcher (Poliioptila melanura)

Black-tailed gnatcatchers generally nest in mesquite thickets or desert riparian scrub (e.g., in smoke tree or catclaw acacia). It was not reported on the project site or transmission line alignment, though suitable habitat is present, particularly along the proposed generator tie-line alignment. It is considered common in the lower Colorado River watershed (most of Arizona and easternmost California; Rosenberg et al. 1991). Black-tailed gnatcatcher is on CDFG's list of Special Animals (CDFG 2009b), but its Natural Diversity Data Base ranking of S4 indicates that it is apparently secure in California. Staff concludes that it may occur year-round on or adjacent to the project site. Staff believes that suitable habitat would be found along the length of Western's existing 161-kV Parker-Blythe #2 transmission line.

Special-Status Mammals

Special-Status Bats

Knowledge of bat distributions and occurrences is sparse. Several special-status bats (pallid bat, western mastiff bat, California leaf-nosed bat, pocketed free-tailed bat, big free-tailed bat, and Townsend's big-eared bat) could use the site for foraging. Roosting habitat for these species varies, but all roost in habitats not available on the project site, such as caves, tunnels, buildings, crevices, foliage of trees, or crevices in cliffs and rock outcrops (see **Biological Resources Table 4**). The majority of adverse impacts to bat populations in the region result from disturbance of roosting or hibernation sites, especially where large numbers of bats congregate; physical closures of old mine shafts, which eliminates roosting habitat; elimination of riparian or desert wash microphyll vegetation which is often productive foraging habitat; more general habitat loss or land use conversion; and agricultural pesticide use which may poison bats or eliminate their prey-base (Pierson & Rainey 1998; Gannon 2003). Bat life histories vary widely. Some species hibernate during winter, or migrate south. During the breeding season, bats generally roost during the day, either alone or in communal roost sites, depending on species. All bats addressed in **Biological Resources Table 4** are insectivorous, catching their prey either on the wing or on the ground. Some species feed mainly over open water where insect production is especially high, but others forage over open shrublands such as found on the project site. Staff saw no evidence of roosting bats at the railroad crossings just north of the project site. No special-status bats are expected to roost on-site, but several species could forage over the site. Staff believes that suitable habitat for special status bats could be found along the length of Western's existing 161-kV Parker-Blythe #2 transmission line.

Colorado Valley Woodrat (*Neotoma albigula venusta*)

Colorado Valley woodrats are found in arid regions of southwestern Arizona and extreme southeastern California (Ingles 1965). Their habitats include creosote bush and other arid shrublands and cactus flats in desert areas, including some areas with lava substrates. Dens are usually constructed of cactus pads and woody material from trees and shrubs; they may also nest in rock crevices or burrows under boulders (Mares 1999). In California, this woodrat is closely associated with dense patches of beavertail cactus (*Opuntia basilaris*) and mesquite (*Prosopis* spp.) (Williams 1986), and often digs burrows under mesquite trees (Ingles 1965). Colorado Valley woodrat is not listed or proposed for listing as threatened or endangered and is not ranked as a species of special concern by CDFG. Furthermore, no evidence indicating that the species was threatened was found by Williams (1986), and no Colorado Valley woodrat account is included in a more recent compilation of California mammals of special concern or watch list (Bolster 1998). However, the CDFG status S1S2 indicates that Colorado Valley woodrat distribution is very restricted in California, possibly to the point of endangerment. No dense stands of mesquite or beavertail cactus were noted on the project site and the probability that Colorado Valley woodrat may occur there is low. Staff believes that suitable habitat could be found along the length of Western's existing 161-kV Parker-Blythe #2 transmission line, particularly at wash crossings.

Nelson's Bighorn Sheep (*Ovis canadensis nelsoni*)

Historically, bighorn sheep ranged widely throughout western North America and were found as far east as Nebraska. Nelson's bighorn sheep, one of three recognized subspecies, are known from the Transverse Ranges, California Desert Ranges, Nevada, northern Arizona, and Utah. It is a BLM Sensitive Species. Threats to Nelson's bighorn sheep include habitat loss or degradation; barriers to local or regional movement such as fencing, drainage canals, highways, and aqueducts; and competition for water with burros and livestock (BLM et al. 2005). Disease spread by domestic livestock has also impacted bighorn sheep in the California desert and continue to threaten populations (BLM and CDFG 2002). Small, isolated populations are at risk of unsustainable predation by mountain lions.

Bighorn sheep are typically found on open, rocky, steep areas used for escape cover and shelter, with available water and herbaceous vegetation for forage. Bighorn sheep are agile in steep, rocky terrain, allowing them to escape predators such as coyotes, golden eagles, and mountain lions (Wehausen 1992). Most Nelson's bighorn sheep populations live between 300 and 4,000 feet in elevation where the annual precipitation is less than 4 inches and daily high temperatures average 104 °F in the summer (Beacham 2000).

Bighorn sheep primarily browse shrubs and graze on native grasses throughout the year. The pulp and fruits of various cacti are eaten during the dry season (Beacham 2000). Bighorn sheep have large rumens relative to their body size, which allow digestion of grasses, even in a dry state (Hanly 1982). This gives them flexibility to select diets that optimize nutrient content from available forage. Consequently, bighorn sheep feed on a large variety of plant species and diet composition varies seasonally and among locations. Nutritional quality of available forage varies greatly during the year; it is most predictably high in late winter and spring (Wehausen 1992), and this period

coincides with the peak of lambing. The lambing season of Nelson's bighorn sheep is typically between January and April (BLM and CDFG 2002).

Surface water is an essential habitat component for Nelson's bighorn sheep. The sheep congregate near dependable water sources from May through October, due to a combination of breeding activities and diminishing water sources (Beacham 2000). It is common for males and females to segregate and occupy different habitats outside the breeding season (Bleich et al. 1997). Females tend to choose particularly steep, safe areas for bearing and initial rearing of lambs. Areas associated with ridge benches or canyon rims adjacent to steep slopes or escarpments are commonly preferred lambing areas if available. Males frequently occupy much less precipitous habitat during the lamb-rearing season (Bleich et al. 1997). Alluvial fan areas are also used for breeding and feeding activities (Beacham 2000).

In the California deserts, Nelson's bighorn sheep occur in partially isolated, localized populations associated with particular mountain ranges. Taken together, these local populations are considered a "metapopulation." A metapopulation is a group of subpopulations that are connected, meaning that animals move from one subpopulation to another. This interchange prevents the subpopulations from being completely isolated; however, these local populations may be comprised of only a few animals and are always vulnerable to local demographic fluctuation and extinction. While individual populations may suffer periodic significant declines, they also may be repopulated as bighorn sheep disperse among mountain ranges by crossing the intermittent valleys. Male bighorn (rams) may disperse among mountain ranges (thus, among subpopulations) during the breeding season (Krausman et al. 1999). Females (ewes) also move among subpopulations, though not as often as the rams. In the California desert, bighorn sheep must remain within access of drinking water during summer. But extensive cool-seasonal dispersal among subpopulations, across valleys, alluvial fans, and bajadas, has been well documented (e.g., Bleich et al. 1990). These dispersal events can serve to recolonize locally extinct populations. Fragmentation of habitat and the loss of movement corridors among partially isolated mountain ranges, including the 37 recognized sub-populations within the NECO planning area, can lead to extirpation of individual subpopulations. The Turtle Mountains to the north of the project site, and the Maria Mountains to the south, are probably occupied by Nelson's bighorn sheep populations, and smaller ranges in the area may become reoccupied by natural immigration or restocked by CDFG (BLM 2007). Conservation and management of habitat corridors is necessary to the Nelson's bighorn sheep's metapopulation biology.

The proposed RSEP project site is on a lower bajada where Nelson's bighorn sheep may range during cool seasons, but it provides no onsite water supply, nor is it near enough to a surface water source for regular warm-season foraging. Vegetation on the site is generally open, and no suitable dense thickets for shaded escape cover are available. Thus, the RSEP site is unlikely to serve as important bighorn sheep habitat. However, Nelson's bighorn sheep are likely to use habitat on the site intermittently during winter, especially as a movement corridor among regional mountain ranges. Wildlife movement is discussed further under **Impacts to Wildlife Movement**, below. Staff believes that suitable foraging and movement habitat for Nelson's bighorn sheep would be found along portions of the length of Western's existing Parker-Blythe #2 transmission line.

Burro Deer (Odocoileus hemionus eremicus)

The burro deer (also known as the desert mule deer) is a subspecies of mule deer endemic to southeastern California, through southern Arizona and New Mexico, and desert regions of mainland Mexico (Mackie et al. 2003). Burro deer tend to have larger home ranges than mule deer in other areas, probably because their desert habitat produces less food. Their home ranges contract during summer, probably because the deer must remain fairly near dependable water sources. Their habitats include desert mountain ranges, bajadas, and flats. The mountainous areas provide favored fawning habitat and more reliable water sources (springs and bedrock sinks) than the flats (Fox and Krausman 1994). Further, montane vegetation provides greater nutritional value than creosote scrub on the flats and bajadas. Dense vegetation is an important habitat element year-round for shaded cover and protection from predators (Tull et al. 2001).

Burro deer require drinking water and generally drink daily during summer. Thus their summer range is limited to areas within a few kilometers of water sources. The proposed RSEP project site is on a lower bajada where burro deer may range during cool seasons, but it provides no onsite water supply, nor is it near enough to a surface water source for regular warm-season foraging. Vegetation on the site is generally open, and no suitable dense thickets for shaded escape cover are available. Thus, the RSEP site is unlikely to serve as important burro deer habitat. However, burro deer are likely to use habitat on the site intermittently during winter, especially as a movement corridor among regional mountain ranges. Wildlife movement is discussed further under **Impacts to Wildlife Movement**, below. Staff believes that suitable foraging and movement habitat for Burro deer would be found along portions of the length of Western's existing 161-kV Parker-Blythe #2 transmission line.

Yuma Mountain Lion (Felis concolor browni)

The Yuma mountain lion is recognized by some authors, but not all, as a distinct subspecies of the widespread North American mountain lion (Pierce and Bleich 2003). It is recognized by CDFG as a Species of Special Concern (CDFG 2009b). Interpretations of its geographic range vary, but by any account it is limited to the Sonoran Desert in southern California and perhaps east into Arizona and south into Mexico (Kucera 1998). The Yuma mountain lion's life history is poorly documented. It is known largely from the bottomlands and foothills of the Colorado River Valley. Its principal prey are burro deer and bighorn sheep, described above and its range and habitat generally coincide with theirs (Cashman et al. 1992). Mountain lions are rare in the lower Colorado River Valley. For example, Germaine et al. (2000) were able to confirm sign of only three individuals during 687 person-days of field survey effort in southwestern Arizona.

There is some concern that the Colorado Desert region may not support a viable mountain lion population, and that lions found in the eastern low desert have dispersed there from surrounding areas. Habitat loss is a serious concern for Yuma mountain lion, for two reasons. First, declining habitat availability and increasing habitat fragmentation affect its long-term population viability. Second, as habitat loss and fragmentation affect burro deer and bighorn sheep, any reduction of the available prey could lead to an insufficient prey base for a viable mountain lion population (Kucera 1998).

As described above for burro deer and Nelson's bighorn sheep, the RSEP site is unlikely to serve as important Yuma mountain lion habitat. However, mountain lions may use habitat on the site intermittently during winter, especially as a movement corridor among regional mountain ranges. Wildlife movement is discussed further under **Impacts to Wildlife Movement**, below. Staff believes that suitable foraging and movement habitat for Yuma mountain lion would be found along portions of the length of Western's existing 161-kV Parker-Blythe #2 transmission line.

American Badger (Taxidea taxus)

American badgers are now uncommon, permanent residents throughout most of the state, including the Colorado Desert. It is recognized by CDFG as a Species of Special Concern. Badger numbers have declined drastically in California in the 20th century due largely to agricultural and urban development, direct and secondary poisoning, and shooting and trapping for control (Williams 1986), though these factors probably have not been important threats to badgers in the Colorado Desert. They are found in open shrubland, forest, and herbaceous habitats with friable soils. In the southwest, badgers are typically associated with creosote bush and sagebrush shrublands. They drink surface water where available but apparently do not require drinking water (Laudenslayer 2007). Mating occurs in late summer or early fall and two to three young are born in March or April (Long 1973). Badgers are fossorial, digging large burrows in dry, friable soils and will use multiple dens/cover burrows within their home range. They have several dens within their home range and move among them daily, although they can use a den for a few days at a time (Sullivan 1996). Cover burrows are an average of 30 feet in length and are approximately 3 feet in depth. Natal dens are larger and more complex than cover dens. Badger home range sizes are dependent upon prey availability and other habitat characteristics. In general, home ranges are several hundred acres in size, though they would likely be larger in the Colorado Desert due to low prey densities. American badger is not known from the project site and, if an active den were to occur on-site, it presumably would have been detected during desert tortoise surveys (Appendix 5.2C of SR 2009a). Even so, badgers could occur in the area, at least during dispersal, and suitable desert scrub habitat is present throughout the project area. Staff believes that suitable habitat would be found along the length of Western's existing 161-kV Parker-Blythe #2 transmission line.

Desert Kit Fox (Vulpes macrotis arsipus)

The desert kit fox can be found in much of the same habitats as the badger. Desert kit fox is not listed as a special-status species by the State of California or the USFWS, but it is protected under Title 14, California Code of Regulations (Title 14, Section 460). Kit foxes are primarily nocturnal, and inhabit open level areas with patchy shrubs. Friable soils are necessary for the construction of dens, which are used throughout the year for cover, thermoregulation, water conservation, and rearing pups. Kit foxes typically produce one litter of about four pups per year, with most pups born February through April (Ahlborn 2000). Desert kit fox is present within the project site (Appendix 5.2C of SR 2009a), and would be expected throughout the site. Estimates of kit fox home range size vary widely, and population densities fluctuate drastically depending on the prey availability, predation pressures, and other factors (Zoellick and Smith 1992; White and Garrott 1999; Arjo et al. 2003). In addition, many kit fox home ranges overlap considerably, often by 20 percent or more (Zoellick and Smith 1992). Therefore, it is

difficult to estimate the actual number of desert kit foxes that may occupy the project site. Staff believes that suitable habitat would be found along the length of Western's existing 161-kV Parker-Blythe #2 transmission line.

Jurisdictional Waters

The following text describes jurisdictional streambeds on the proposed solar generator site and associated generator tie-line alignment and substation. No field surveys or streambed delineation of the Western Parker-Blythe #2 transmission line have been provided for staff's review. Based on a review of online aerial images, staff believes that the transmission line crosses numerous desert washes and that project activities such as road widening, pole access, and OGHW installation that may occur within those washes may be subject to regulation under Section 1600 of the California Fish and Game Code or Section 404 of the Federal Clean Water Act. Absent baseline data for this project component, staff does not evaluate potential project impacts to those resources here.

The project site is located on a bajada on the north side of Rice Valley that supports numerous drainages that flow from the surrounding mountains. Rice Valley is a drainage sink with no broader hydrological connectivity. Streams, washes, and playas are dry most of the year with surface water present only after storm events. There are no perennial surface water sources and there is no evidence that a lake ever formed in the valley during wetter climatic periods (SR 2009a; Attachment DR60-1 of CH2MHill 2010a).

Due to the arid conditions of the area, most of the surface waters in the region are ephemeral streams. All channels observed in the RSEP site and crossed by the proposed transmission line are ephemeral (SR 2009a; Attachment DR60-1 of CH2MHill 2010a). These ephemeral streams are typically dry washes that only flow briefly, in response to precipitation. Regional storms, which generally occur in the winter months, are typically of low intensity, but can create short-lived ephemeral streams and cause significant flooding in the valley. Intense summer thunderstorms can also produce flooding in the low-lying valleys. During most storms, ephemeral streams may only run surface water for a couple of hours, though some may run for several days during an uncommon series of several heavy winter storms.

Wetlands are not present on the solar generator site or along the proposed generator tie-line alignment. U.S. Geological Survey (USGS) maps of the project area show four intermittent, blue-line channels in the project area. Two blue-line channels enter the property from north of the RSEP site, one at the northwest corner and one near the northeast corner. These drainages were rerouted to the west and east, respectively, by levees to protect the airfield. These levees have breached since then, now allowing runoff to flow across the property. Two additional blue-line ephemeral channels originate in the RSEP facility boundary and flow south towards the bottom of Rice Valley (Attachment DR60-1 of CH2MHill 2010a).

In addition to the four ephemeral, blue-line channels, there are numerous other desert washes that originate on-site and drain southward across the RSEP site. All of these channels are ephemeral (Attachment DR60-1 of CH2MHill 2010a). In total there are

75.4 acres of state-jurisdictional streambeds (i.e., ephemeral washes) within the 1410 acre solar generator site. Staff concludes all of this streambed acreage would be directly or indirectly affected by project construction and operation. In addition, there are 2.1 acres of state-jurisdictional streambeds outside the perimeter fence that would be directly affected by permanent or long-term project components (i.e., channel diversions, access road, and temporary logistics /laydown area).

The generator tie-line corridor crosses two intermittent blue-line channels within the RSEP facility boundary and seven between the boundary and where the line intersects Rice Valley Road (Attachment DR60-1 of CH2MHill 2010a). These channels flow in a south-southwest direction until they lose definition near the bottom of Rice Valley. In total there are approximately 5.3 acres of state-jurisdictional streambeds (i.e., ephemeral washes) within the generator tie-line alignment that could be affected by project construction. Acreage and character of any jurisdictional waters on Western's existing Parker-Blythe #2 transmission line are unknown.

Field studies conducted by the applicant found that the USGS mapping accurately reflects conditions on the solar generator site, generator tie-line alignment, and substation site. None of the drainage features are tributary to a traditionally navigable water. They do not cross state lines or Tribal lands. The applicant concluded that the drainage features that cross through and originate on the RSEP project site, as well as those crossed by the transmission line route, are isolated intrastate waters with no apparent interstate or foreign commerce connection. As such, the Army Corps of Engineers (USACE) has determined that there are no waters of the US subject to jurisdiction under the Clean Water Act on the project site (USACE 2010). The applicant has submitted a Lake and Streambed Alteration Notification to CDFG and Energy Commission staff (CH2MHill 2010f) for proposed alterations at the solar generator site, generator tie-line, and interconnector substation. State or federally jurisdictional streambeds or wetlands that may be located along the existing 161-kV Parker-Blythe transmission line have not been delineated and are not evaluated in this SA/DEIS.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

Biological Resources Table 5 summarizes the impacts to biological resources resulting from construction and operation of the RSEP solar generator, generator tie-line, and interconnector substation, and provides conditions of certification to mitigate these impacts. Staff's recommended conditions of certification are discussed in more detail later in this analysis.

Biological Resources Table 5
Summary of Solar Generator, Generator Tie-Line, and Interconnector Substation Impacts/Mitigation

Biological Resource	Impact/Mitigation
Colorado Desert Plant Communities and Wildlife Habitat	<p>Impact: Permanent and long-term loss and fragmentation of a total of approximately 1,770 acres of native vegetation; potential direct impacts to terrestrial wildlife by heavy equipment and grading; increased risk of road kill; increased disturbance/dust to nearby vegetation and wildlife; spread of non-native invasive weeds.</p> <p>Mitigation: Avoidance and minimization measures (BIO-1 through BIO-9); revegetation (BIO-10); weed management (BIO-11); desert tortoise compensatory mitigation (BIO-16).</p>
Special-Status Plants	<p>Impact: Potential loss and fragmentation of habitat, potential loss of individuals.</p> <p>Mitigation: Avoidance and minimization measures (BIO-1 through BIO-9); restoration/compensation (BIO-10); weed management (BIO-11); surveys for rare plants prior to ground disturbance and avoidance of rare plants (BIO-12); compensation if needed for rare plant habitat (BIO-12).</p>
Common Wildlife, including Migratory and Resident Birds	<p>Impact: Potential mortality or disturbance during construction and operation, loss or fragmentation of habitat, displacement, disruption of movement, poisoning or drowning at evaporation ponds.</p> <p>Mitigation: Avoidance and minimization measures (BIO-1 through BIO-9); restoration/compensation (BIO-10); weed management (BIO-11); indirect benefit from desert tortoise compensatory mitigation (BIO-16); Evaporation Pond Design, Monitoring, and Management Plan (BIO-24).</p>
Waters of the State / Waters of the US	<p>Impact: Permanent and long-term impacts to approximately 82.8 acres of waters of the State (excluding additional jurisdictional waters on the Parker-Blythe #2 Transmission Line); no jurisdictional waters of the US are present on the solar generator site, generator tie-line alignment, or interconnector substation site. Locations and potential impacts to state or federally jurisdictional waters on the Parker-Blythe #2 transmission line are unknown.</p> <p>Mitigation: Acquisition of offsite State jurisdictional waters, the implementation of Best Management Practices to protect drainages, elimination of proposed detention basins, and nonnative vegetation removal (BIO-22); conservation and enhancement of waters of the State occurring on desert tortoise compensatory mitigation lands (BIO-16).</p>
Special-Status Wildlife	
Cheeseweed Owlfly	<p>Impact: Loss or fragmentation of habitat, if present.</p> <p>Mitigation: Avoidance and minimization measures (BIO-1 through BIO-9); restoration/compensation (BIO-10); potential indirect benefit through desert tortoise compensatory mitigation (BIO-16).</p>

Biological Resource	Impact/Mitigation
Couch's Spadefoot	<p>Impact: Loss or fragmentation of habitat, if present.</p> <p>Mitigation: Avoidance and minimization measures (BIO-1 through BIO-9); restoration/compensation (BIO-10); potential indirect benefit through desert tortoise compensatory mitigation (BIO-16).</p>
Mojave Fringe-Toed Lizard	<p>Impact: Loss or fragmentation of habitat, if present in project area.</p> <p>Mitigation: Avoidance and minimization measures (BIO-1 through BIO-9); restoration/compensation (BIO-10).</p>
Gila Monster and Rosy Boa	<p>Impact: Potential mortality and disturbance; loss of habitat and habitat fragmentation, if present.</p> <p>Mitigation: Avoidance and minimization measures (BIO-1 through BIO-9); restoration/compensation (BIO-10); capture and relocation if found within work areas (BIO-14); potential indirect benefit through desert tortoise compensatory mitigation (BIO-16).</p>
Desert Tortoise	<p>Impact: Habitat loss and fragmentation; disruption of movement corridors; potential take of individuals during operation and construction; increased risk of predation from ravens and other predators; increased road kill hazard from construction and operations traffic.</p> <p>Mitigation: Avoidance and minimization measures (BIO-1 through BIO-9); restoration/compensation (BIO-10); clearance surveys and exclusion fencing (BIO-14); Translocation Plan (BIO-15); off-site habitat acquisition and conservation (BIO-16); Raven Monitoring, Management, and Control Plan (BIO-17).</p>
Golden Eagle	<p>Impact: Loss of foraging habitat; disruption of foraging activities; collisions or incineration; electrocution.</p> <p>Mitigation: General avoidance and minimization measures (BIO-1 through BIO-9); restoration/compensation (BIO-10); potential indirect benefit through desert tortoise compensatory mitigation (BIO-16); golden eagle nest site surveys (BIO-18); Avian Protection Plan and monitoring bird impacts from solar technology (BIO-25).</p>
Prairie Falcon	<p>Impact: Loss of foraging habitat; disruption of foraging activities; collisions or incineration; electrocution.</p> <p>Mitigation: General avoidance and minimization measures (BIO-1 through BIO-9); restoration/compensation (BIO-10); potential indirect benefit through desert tortoise compensatory mitigation (BIO-16); Avian Protection Plan and monitoring bird impacts from solar technology (BIO-25).</p>

Biological Resource	Impact/Mitigation
Burrowing Owl	<p>Impact: Loss of wintering burrow sites; potential loss of nest, eggs, or young if owls breed onsite; potential loss of breeding and/or foraging habitat; potential disturbance of nesting and foraging activities for populations on and near the project site; exposure to toxins in the evaporation ponds</p> <p>Mitigation: Implement burrowing owl impact avoidance and mitigation measures; pre-construction surveys; detection and avoidance of active burrows and, if necessary passive relocation measures, including creation of artificial burrows for displaced individuals; and burrowing owl habitat compensation (BIO-19); potential indirect benefit through desert tortoise compensatory mitigation (BIO-16).</p>
Other Migratory/Special-Status Birds Loggerhead Shrike Le Conte's Thrasher Crissal Thrasher Black-Tailed Gnatcatcher	<p>Impact: Disturbance of nesting activities; potential loss of nest, eggs, or young; loss of breeding and foraging habitat; potential mortality due to collisions and/or incineration with solar infrastructure; exposure to toxins in the evaporation ponds.</p> <p>Mitigation: General avoidance and minimization measures (BIO-1 through BIO-9); restoration/compensation (BIO-10); conduct pre-construction nesting surveys, implement avoidance measures (BIO-13); potential indirect benefit through desert tortoise compensatory mitigation (BIO-16); Avian Protection Plan and monitoring bird impacts from solar technology (BIO-25); Evaporation Pond Design, Monitoring, and Management Plan (BIO-24).</p>
Bird Collisions, Electrocution, Incineration	<p>Impact: Avian species, including special-status species, could be subject to mortality due to collisions and/or electrocution on project transmission lines and collisions and/or incineration with heliostats and the central receiving tower.</p> <p>Mitigation: Transmission lines and all electrical components shall be designed, installed, and maintained in accordance with the Avian Power Line Interaction Committee's (APLIC's) <i>Suggested Practices for Avian Protection on Power Lines</i> (APLIC 2006) and <i>Mitigating Bird Collisions with Power Lines</i> (APLIC 2004) (BIO-8); Avian Protection Plan and monitoring bird impacts from solar technology (BIO-25).</p>
Nelson's Bighorn Sheep, Burro Deer, and Yuma Mountain Lion	<p>Impact: Habitat loss and fragmentation; disturbance from construction activities, noise, and lighting; interference with movement and behavioral modifications due to human presence.</p> <p>Mitigation: Avoidance and minimization measures (BIO-1 through BIO-9); restoration/compensation (BIO-10); potential indirect benefit through desert tortoise compensatory mitigation (BIO-16).</p>
American Badger and Desert Kit Fox	<p>Impact: Potential loss and fragmentation of habitat, loss of foraging grounds, crushing or entombing of animals during construction.</p> <p>Mitigation: Conduct pre-construction surveys and implement avoidance measures for American badger and desert kit fox (BIO-20); potential indirect benefit through desert tortoise compensatory mitigation (BIO-16).</p>

Biological Resource	Impact/Mitigation
Special-Status Bats	<p>Impact: No significant impact.</p> <p>Mitigation: None recommended; anticipated benefit through Avian and Bat Protection Plan and monitoring bird impacts from solar technology (BIO-25).</p>
Wildlife Movement Corridors	<p>Impact: Interference with wildlife movement across project site due to permanent exclusion fencing.</p> <p>Mitigation: Redesign logistics and lay down area to provide buffer between project fence and SR-62 during construction (BIO-21).</p>

Four of staff's recommended Conditions of Certification would require the Project owner to acquire compensation lands to mitigate the Project's impacts to biological resources. Detailed discussion of compensation habitat is provided in text that follows and in Conditions of Certification cited here. The most significant of these is **BIO-16**, Desert Tortoise Compensatory Mitigation. The others are **BIO-12**, **BIO-19**, and **BIO-22**. **BIO-12** (Special-Status Plant Impact Avoidance and Minimization) provides the option of mitigating impacts to rare plants that may be discovered on the site during late-season botanical surveys through habitat compensation. **BIO-19** (Burrowing Owl Impact Avoidance, Minimization, and Compensation Measures) would require compensation for Project impacts to this animal. **BIO-22** (Streambed Impact Minimization and Compensation Measures) would require compensation for state-jurisdictional streambed acreage impacted by the project. In each of these conditions, staff recommends a financial security to ensure adequate funding to acquire and manage the compensation lands. Staff recommends that this security should be equal to staff's estimated costs for habitat compensation and management. Staff recognizes that some potential compensation lands may support more than one of these resources, and staff recommends that, wherever applicable, the Project owner should seek compensation lands meeting selection criteria for more than one of these resources, as described in these Conditions of Certification, below. However, pending acquisition of compensation lands, staff recommends separate securities for each resource.

Staff has calculated the acreage and estimated costs for desert tortoise compensation lands, as described in Condition of Certification **BIO-16**. Staff provides estimates of acreage and costs for burrowing owl habitat compensation in **BIO-19** and for streambed compensation in **BIO-22**. Any potential compensation acreage for rare plants, pursuant to **BIO-12**, would be determined upon completion of late-season field surveys and cannot be estimated at this time. Staff anticipates that compensation lands for burrowing owls, rare plants, and streambeds would be "nested" within desert tortoise compensation lands, avoiding necessity for additional compensation lands. However, further compensation lands may be required dependent upon the extent of state jurisdictional waters on the desert tortoise compensation lands. Therefore, staff does not recommend "nesting" financial securities for these compensation lands. **Biological Resources Table 6**, below, presents the basis for staff's compensatory cost estimates in each of these recommended conditions of certification.

Biological Resources Table 6
Habitat Compensation Cost Estimates: Conditions of Certification: BIO-12,
BIO-16, BIO-19 and BIO-22 ¹

	Task	Cost
1.	Land Acquisition	\$500 per acre ²
2.	Level 1 Environmental Site Assessment	\$3,000 per parcel ³
3.	Appraisal	\$5,000 per parcel
4.	Initial site work - clean-up, enhancement , restoration	\$250 per acre ⁴
5.	Closing and Escrow Costs – 2 transactions at \$2,500 each; landowner to 3 rd party and 3 rd party to agency	\$5,000 per parcel
6.	Biological survey for determining mitigation value of land (habitat based with species specific augmentation)	\$20,000 per parcel
7.	3 rd party administrative costs - includes staff time to work with agencies and landowners; develop management plan; oversee land transaction; organizational reporting and due diligence; review of acquisition documents; assembling acres to acquire....	10% of land acquisition cost (#1)
8.	Agency costs to review and determine accepting land donation - includes 2 physical inspections; review and approval of the Level 1 ESA assessment; review of all title documents; drafting deed and deed restrictions; issue escrow instructions; mapping the parcels....	15% of land acquisition costs (#1) × 1.17 (17% of the 15% for overhead)
<i>SUBTOTAL A - Acquisition & Initial Site Work</i>		
9.	Long-term Management and Maintenance (LTMM) Fund - includes land management; enforcement and defense of easement or title [short and long term]; monitoring....	\$1,450 per acre ⁵
<i>SUBTOTAL B - Acquisition, Initial Site Work, & LTMM</i>		
NFWF Fees		
10.	Establish the project specific account	\$12,000
11.	Pre-proposal Modified RFP or RFP processing ⁶	\$30,000
12.	NFWF management fee for acquisition & initial site work	3% of SUBTOTAL A
13.	NFWF Management fee for LTMM Fund	1% of LTMM Fund
<i>TOTAL for deposit in REAT-NFWF Project Specific Account</i>		

1. Estimates prepared in consultation with CDFG, USFWS, and BLM. All costs are best estimates as of summer 2010. Actual costs will be determined at the time of the transactions and may change the funding needed to implement the required mitigation obligation. Note: regardless of the estimates, the developer is responsible for providing adequate funding to implement the required mitigation.

2. Generalized estimate taking into consideration a likely jump in land costs due to demand, and an 18-24 month window to acquire the land after agency decisions are made. If the agencies, developer, or 3rd party has better, credible information on land costs in the specific area where project-specific mitigation lands are likely to be purchased, that data overrides this general estimate. Note: regardless of the estimates, the developer is responsible for providing adequate funding to implement the required mitigation.

3. For the purposes of determining costs, a parcel is 160 acres (based on input from CDD).

4. Based on information from CDFG.

5. Estimate for purposes of calculating general costs. The actual long term management and maintenance costs will be determined using a Property Assessment Report (PAR) tailored to the specific acquisition.

6. If determined necessary by the REAT agencies if multiple 3rd parties have expressed interest; for transparency and objective selection of 3rd party to carry out acquisition.

Overview of Impacts to Vegetation and Wildlife

Construction of the RSEP would result in the permanent land use conversion of native vegetation communities and potential loss of special-status plant and animal species. Permanent and long-term habitat loss as defined by staff involves impacts that would not recover within 5 years. The RSEP would have long-term impacts associated with project features (e.g., solar generator site, new interconnector substation, upgrades to the existing 161-kV Parker-Blythe #2 transmission line, new generator tie-line construction, new access roads, altered drainage features, and required maintenance activities that would routinely disturb wildlife and vegetation) that would continue throughout the life of the project, as well as habitat degradation that would persist for decades following project closure.

Impacts during Construction

Construction Impacts to Vegetation

Impact analyses typically characterize effects to plant communities as temporary or permanent. Permanent impacts generally refer to areas to be paved or otherwise precluded from most natural habitat function throughout the life of a proposed project. Temporary impacts generally refer to areas to be disturbed during project construction, but allowed to return to a more natural condition after initial construction disturbance. Mitigation ratios for temporary impacts may be less than those for permanent impacts, especially if revegetation or ecological restoration is employed. In the desert ecosystem, the interpretation of permanent and temporary impacts needs to reflect the slow recovery rates of native plant communities. Natural recovery rates from disturbance in these systems depend on the nature and severity of the impact and on weather conditions in the subsequent years. For example, creosote bushes can resprout a full canopy within five years after damage from heavy vehicle traffic (Gibson et al. 2004), but more severe damage involving vegetation removal and soil disturbance can take from 50 to 300 years for partial recovery; complete ecosystem recovery may require over 3,000 years (Lovich and Bainbridge 1999). In this analysis, an impact that might be considered temporary in other parts of California will be considered long-term or permanent due to these very slow natural recovery rates.

Clearing and grubbing of native vegetation (i.e., removal of shrubs and their roots) would be performed for the construction of permanent access roads, mirror structure installation, and other project facilities throughout the proposed solar field site, throughout much of the proposed construction facilities and logistics area, at each tower or pull site and for the new access road along the proposed transmission line alignment, and at the interconnection substation. Outside of access roads and maintenance tracks, vegetation would be cut to ground level as needed for construction but would leave the roots intact, allowing for some regrowth. During project operations, these shrubs would be mowed to provide clearance for heliostat function. Native shrubs undergoing repeated mowing would be weakened and diminished in size, degrading or eliminating their value as wildlife habitat. Overall impacts of these construction, operations, and maintenance procedures would cause substantial degradation to native vegetation and wildlife habitat.

Project construction would result in permanent and long-term impacts to approximately 1,743 to 1770 acres of desert shrubland (excluding the 6-acre unvegetated concrete pad; see **Biological Resources Tables 2 and 3**). In addition to the direct impacts to vegetation, project construction and operation would have several indirect impacts to native vegetation, including introduction or spread of invasive weeds and increased dust. These are described further below.

Invasive, Non-Native, and Noxious Weeds

Weeds are defined here to include species of non-native plants identified on the weed lists of the California Department of Food and Agriculture (CDFA 2007), the California Invasive Plant Council, or those weeds of special concern identified by BLM. The spread of invasive plants is a major threat to biological resources in the California desert because non-native plants can displace native plants, increase the threat of wildfire, supplant wildlife foods that are important to herbivorous species, alter the habitat structure and ecological function of wetland, riparian, and desert wash communities, and invade threaten special-status plant occurrences and habitat (Zouhar et al 2008; Lovich 1998; Lovich et al 1997).

New weed species can be introduced to an area, or weeds already present on-site can spread due to construction and operation of the proposed facility.

Construction activities and soil disturbance tend to introduce non-native invasive plant species into new areas and to facilitate their proliferation and spread. New introductions occur when seed are inadvertently introduced to a site, most often with mulch, hay bales, or wattles used for erosion control, or when they are carried on equipment tires from off-site. Many invasive non-native species are adapted to and promoted by soil disturbance (Lathrop & Archibald 1980). Once introduced, they can out-compete native species because of minimal water requirements, high germination potential and high seed production (Beatley 1966) and can become locally dominant, representing a serious threat to native desert ecosystems (Abella et al. 2008). Invasive weeds generally spread most readily in disturbed, graded, or cultivated soils, including soils disturbed by construction equipment. Thus, the proposed RSEP, including solar generation construction and associated transmission line and other facilities, would be expected to introduce or facilitate the spread of invasive non-native plants. Without weed control, staff anticipates that weeds already present in the area would increase their abundance in soils disturbed by project construction throughout the project site and along the linear facilities, and that construction equipment could import new invasive species from off-site.

Undisturbed desert habitat has been vulnerable to a limited suite of alien plant species capable of invading it. But the hot and arid environment; undependable timing and amount of annual precipitation; and often saline or alkaline soils limit the range of invasive species capable of naturalization there (Mack 2002). Certain aspects of the proposed project would change those conditions, probably creating habitat more suited to a wider variety of invasive plants and to greater abundance of the invasive species already present in the area. Shade beneath the mirror structures would alter the micro-environments, favoring weedy annual species. Studies conducted in the Sonoran and Mojave Deserts have demonstrated that shading resulted in a cooler, moister microhabitat below and near structures (Smith 1984, Smith et al. 1987). Shading and

wind deflection caused by the structures decrease soil temperature extremes and decrease evaporation from soil surfaces. The addition of water due to a regular mirror washing regimen also increases the humidity of the microhabitat around the solar structures. This change from the normal arid desert environment would not favor the native arid-adapted species and, instead, would allow weedy ephemerals to colonize (Smith 1984).

Numerous invasive weeds have already become widespread throughout the Mojave and Colorado deserts and prevention of further spread is impracticable. Examples of these species include red brome, cheat grass, Mediterranean schismus, red-stemmed filaree, Sahara mustard, and Russian thistle. Other invasive species (e.g., saltcedar) are damaging to specific habitat types but pose little or no threat to widespread upland desert habitat. Weeds were relatively low in abundance and diversity throughout the RSEP project area. Staff anticipated that the following seven invasive weed species would be likely to invade disturbed soils on the proposed solar generation site and transmission line alignment. Once established, these or other invasive weeds would likely spread beyond the project boundaries into surrounding undisturbed desert lands.

- **Sahara mustard** (*Brassica tournefortii*) occurs occasionally to commonly throughout the general area; Sahara mustard is of high concern; Cal-IPC has declared this plant highly invasive (Cal-IPC 2006) and recommends that it should be eradicated whenever encountered.
- Annual grasses, including **red brome** (*Bromus madritensis* ssp. *rubens*), **cheatgrass** (*B. tectorum*), and especially **Mediterranean grass** (*Schismus* spp.) are widespread, though at only low cover, in the project area. Red brome is an introduced Eurasian grass adapted to microhabitats that, in desert environments, can be found in partial shade (e.g., at the bases of desert shrubs or near structures). It can also form carpet cover in pockets of fine grained soils in rough terrain of the bajada. It is widespread and abundant in the Mojave Desert, but less so in the Colorado Desert. Its seeds can disperse readily and across large distances. Cal-IPC has declared this plant highly invasive (Cal-IPC 2006). Cheat grass is a closely related species, occurring occasionally at low cover throughout the general area. It is also highly invasive (Cal-IPC 2006). Mediterranean grass is patchily distributed throughout the project site. Cal-IPC has determined that this plant has a limited invasiveness rating in California (Cal-IPC 2006). Because of their widespread distribution, the BLM and other agencies do not consider these and other annual grasses to be feasible for general control (i.e., it is not presently feasible to control them in wildlands). It is therefore important to prevent the project site from becoming a source population, leading to increasing invasions in surrounding lands.
- **Russian thistle, tumbleweed** (*Salsola* spp.) is a common invasive species in disturbed soils. More so than most other invasive species, Russian thistle tends to be restricted to roadway shoulders and other sites where the soil has been recently disturbed (i.e., within a few years). Cal-IPC has determined that this plant has a limited invasiveness rating in California (Cal-IPC 2006). There is a high potential that Russian thistle could become established in the construction area and it should be eradicated if observed.
- **London rocket** (*Sisymbrium irio*) is widespread throughout the warm deserts of North America. Cal-IPC has declared this plant moderately invasive (Cal-IPC 2006).

More so than the other invasive herbs, it tends to be in slightly mesic or shaded sites around structures, and monitoring for this species should particularly focus on moist and shaded areas around the mirror structures.

- **Mediterranean tamarisk, saltcedar** (*Tamarix ramosissima*), it is a riparian plant and is therefore restricted to habitats where there is perennial soil water availability (though often no surface water). Cal-IPC has declared this plant highly invasive (Cal-IPC 2006).
- **Red-stemmed filaree, or storksbill** (*Erodium cicutarium*) is a widespread annual species common in disturbed habitats and often on undisturbed desert uplands. It has a limited overall rating by Cal-IPC, generally because the ecological impacts of the species are minor. Because of its widespread distribution, eradication of filaree in wildlands is not considered feasible.

To avoid and minimize the spread of existing weeds and the introduction of new ones, an active weed management strategy and control methods must be implemented. Implementation of Energy Commission staff's proposed Conditions of Certification **BIO-8** (Impact Avoidance and Minimization Measures), **BIO-10** (Revegetation Plan and Compensation for Impacts to Native Vegetation Communities), and **BIO-11** (Weed Management Plan) would avoid, minimize, and compensate for impacts related to weed species on/near the site and would reduce the impact of weeds to less-than-significant levels under CEQA.

Dust

Disturbance of the soil's surface caused by construction traffic, operations traffic, and other activities such as mirror washing would result in increased wind erosion of the soil. Aeolian transport of dust and sand can result in the degradation of soil and vegetation over a widening area (Okin et al. 2001). Dust can have deleterious physiological effects on plants and may affect their productivity and nutritional qualities (Sharifi et al. 1997; 1999). Aeolian transport of dust and sand can kill plants by burial and abrasion, interrupt natural processes of nutrient accumulation, and allow the loss of soil resources. The destruction of plants and soil crusts by windblown sand and dust exacerbates the erodibility of the soil and accelerates the loss of nutrients (Okin et al. 2001). The impacts of increased dust and other construction impacts can be minimized with implementation of staff's proposed Condition of Certification **BIO-8** (Impact Avoidance and Minimization Measures) to less than CEQA significant levels.

Energy Commission staff considers the direct and indirect impacts to native plant communities from construction of the project to be significant. The following Conditions of Certification are proposed to reduce impacts to vegetation: **BIO-1** (Designated Biologist Selection), which states the minimum qualifications to the satisfaction of the Energy Commission's Compliance Project Manager (CPM); **BIO-2** (Designated Biologist Duties), which outlines the duties performed during any site mobilization, ground disturbance, grading, construction, operation, closure, and restoration activities; **BIO-3** (Biological Monitor Qualifications); **BIO-4** (Biological Monitor Duties), in which the Biological Monitor assists the Designated Biologist during any site mobilization, ground disturbance, grading, construction, operation, closure, and restoration activities; **BIO-5** (Designated Biologist and Biological Monitor Authority), in which the Designated

Biologist and Biological Monitor can stop any activities that would cause an adverse impact to biological resources; **BIO-6** (Worker Environmental Awareness Program), in which workers on the project site or any related facilities are informed about sensitive biological resources; **BIO-7** (Biological Resources Mitigation Implementation and Monitoring Plan), which identifies all biological resources mitigation, monitoring, compliance measures, Conditions of Certification, and permits; **BIO-8** (Impact Avoidance and Minimization Measures), in which all feasible measures, including lighting and dust control, which avoid or minimize impacts to the local biological resources are incorporated in any modification or finalization of project design; **BIO-9** (Compliance Verification); **BIO-10** (Revegetation Plan and Compensation for Impacts to Native Vegetation Communities); **BIO-11** (Weed Management Plan), which would require preparation and implementation of a weed management plan; and in other proposed conditions of certification described in the following sections. Implementation of these measures would reduce impacts of the proposed project to less-than-significant levels under CEQA. In addition, staff's proposed Condition of Certification **BIO-16**, the Desert Tortoise Compensatory Mitigation, requires the acquisition, management, and preservation of similar habitats of equal or greater quality at a 1:1 ratio for permanent impacts to the solar field site and a 3:1 ratio for permanent impacts along the transmission line route and at the interconnection substation. These mitigation lands would provide similar habitat, including vegetation communities, as would be impacted by the RSEP, and preservation of these desert shrublands would compensate for impacts on site. Staff concludes that implementation of these measures would reduce impacts to native plant communities to less than significant levels under CEQA by minimizing vegetation impacts to the extent practicable; revegetating temporarily disturbed areas; controlling invasive weeds and preventing infestations by newly introduced weeds; and providing for long-term conservation and management of native vegetation on desert tortoise compensation lands.

Construction Impacts to Special-Status Plants

Four special-status plant species have been documented on the proposed project site (SR 2009a; Sycamore Environmental Consultants 2010). Staff has reviewed the AFC and its appendices; the applicant's responses to Data Requests; and recent botanical literature to evaluate potential project impacts to these species (see **Special-Status Plants**, above). Staff concludes that adverse impacts to Harwood's milk-vetch, should they occur, would be significant under CEQA and would warrant mitigation. Staff concludes that the proposed RSEP either would not impact chaparral sand-verbena, Utah cynanchum, and Wiggins' cholla, or, if adverse impacts were to occur, they would be less than significant under CEQA and would not warrant mitigation measures.

Staff notes that the seasonal and irregular nature of most plants' life histories, and the scheduling of the field surveys described in the AFC limit staff's ability to interpret the data as submitted for some later-flowering species, and that no botanical surveys have been conducted along the existing 161 kV Western Parker-Blythe #2 transmission line alignment. Staff's recommended **Condition of Certification BIO-12** would require additional late-season field surveys on the solar generator site, generator tie-line alignment, and interconnector substation site, and would require new botanical surveys on the existing 161 kV Western Parker-Blythe #2 transmission line alignment. There is a low to moderate probability that additional special-status plants may be discovered

within the solar generator site or along the generator tie-line alignment during these surveys. The potential for additional special status plant occurrences on the existing 161 kV Western Parker-Blythe #2 transmission line alignment is unknown. Staff's recommended **Condition of Certification BIO-12** provides a strategy to detect special status occurrences, avoid impacts to them, evaluate significance for any impacts in cases where avoidance is not possible, and to mitigate those impacts below a level of significance.

For special-status plants known from the project site, staff's conclusion of CEQA significance was based on an analysis of impacts to these species in light of the variables described below. Staff's recommended **Condition of Certification BIO-12** would apply the same criteria to evaluate significance of potential impacts to any additional special status plant occurrences discovered in follow-up field surveys.

- Conservation status and taxonomic status of each taxon, as reported by CNPS (2010); CDFG (2010b); and current botanical literature (as described for each species under **Special-Status Plants**, above);
- Proportion of occurrences that may be lost and indirectly affected by the project relative to the documented occurrences and distribution of these species in California;
- Extent of occurrence on-site (i.e., number of documented locations);
- Habitat quality;
- Cumulative effects and indirect threats to remaining occurrences; and
- Peripheral population status.

Proportion of Occurrences Affected and Occurrence Size. Plants and other sessile organisms are particularly vulnerable to the effects of habitat fragmentation. Small habitat patches ("fragments") can support only small populations, which are more vulnerable to extinction. Even minor habitat changes or other effects can cause extinction of a small, localized plant population. Harwood's milk-vetch is ranked on CNPS List 2, indicating that its occurrences in California, including its occurrences on the proposed transmission line alignment, are geographically marginal relative to its core populations outside the state. For this species, the Colorado Desert populations represent a substantial portion of its total known distribution within California. Adverse effects to occurrences in the project area could affect a substantial portion of its regional populations and make it more vulnerable to extirpation within the state.

Habitat Quality. Staff notes that the habitat along the proposed transmission line alignment is generally undisturbed and is immediately adjacent to a designated BLM Wilderness area. Habit on the solar generator site, by contrast, has been disturbed by historic land uses (described above).

Threats. Threats to special-status plants in the region include land use changes, grazing, ORV use, and non-native plants (CDFG 2010a; CNPS 2010). The proposed transmission line alignment is relatively remote and unaffected by these threats. There appears to have been little habitat damage by grazing, cross-country ORVs, or weed invasions along the proposed alignment.

Status as Peripheral Populations. California occupies an important biogeographic location and zone of ecological transition on the Pacific coast of North America, and so its floristic diversity includes many widespread taxa at the edges of their geographic ranges. The CNPS List 2 is defined as species which are rare in California but more common elsewhere in their geographic ranges. That is, these are species whose California occurrences are at the geographic limits of their ranges. Harwood's milk-vetch, the CNPS List 2 species occurring in the project area, is at the western limits of its geographic distribution centered farther east.

Plant populations at the peripheries of their geographic ranges, as the CNPS List 2 species are, may have special conservation and biodiversity values. They tend to be more genetically and ecologically divergent than core populations, and often are ecologically distinctive (Leppig & White 2006). Peripheral populations may serve to increase or maintain genetic variation for the species as a whole, and contribute to long-term species survival and adaptation, especially in changing environments (Channel and Lomolino 2000; Leppig & White 2006). Yet peripheral plant populations are at greater risk of extirpation than core populations because they are smaller in areal extent, smaller in numbers of plants, and often in locations where habitat conditions are at the margins of their physiological limits.

CEQA Significance and CNPS Status. Harwood's milk-vetch is not listed under the California or federal Endangered Species Acts. But, under significance criteria adopted by the Energy Commission in this SA/DEIS, project impacts to this species, if not mitigated, would be considered significant pursuant to CEQA. The Energy Commission and other state agencies such as CDFG and the California Department of Water Resources have a history of requiring mitigation for impacts to special-status plants such as these.

Under Section 15380 of the CEQA guidelines, a species may be considered endangered, rare or threatened, if it can be shown to meet the criteria for state or federal listing. "CEQA Section 15380 provides that a plant or animal species may be treated as 'rare or endangered' even if not on one of the official lists if, for example, it is likely to become endangered in the foreseeable future."

The California Native Plant Society (CNPS) cooperates under a memorandum of understanding with CDFG to identify which plants may be rare or threatened, evaluate threats to them, share occurrence data, and plan protective measures. In this role, CNPS evaluates plant taxa according to abundance, distribution, and threats, and it ranks rare species on a series of lists. The joint CNPS Rare Plant Program and CDFG's CNDDDB Plant Status Review Process for CNPS List and CDFG Special Plants List status is a rigorous review process that evaluates existing literature, reviews herbarium collections, and communicates with experts before making a recommendation for listing. A summary of information on each candidate taxon is reviewed by a network of California botanists, representing state and federal agencies, environmental consulting firms, academic institutions, CNPS, and other conservation organizations. All of the CNPS List 1B and 2 plants in the project area are also included in the CDFG Special Plants List (CDFG 2010b) and are tracked by CDFG's CNDDDB (CDFG 2010a). The *CNPS Inventory* has been a broadly recognized and accepted source of science-based

information on the rarity, endangerment, and distribution of California special-status plants since its first edition in 1974. The Energy Commission's regulations reference CNPS Lists in the definition of "species of special concern" (California Code of Regulations, Title 20, section 1702 (q) and (v)), and the BLM has a policy of designating all CNPS List 1B plants, unless specifically excluded by the BLM State Director, as BLM Sensitive (BLM 2009b). By CNPS's standards, the plants on CNPS Lists 1A, 1B, and 2 meet the definitions of Sections 2062 and 2067 (CESA) of the California Fish and Game Code, and are eligible for state listing (CNPS 2001). The Energy Commission considers those plants appearing on CNPS List 1B or 2 to meet CEQA's Section 15380 criteria, and adverse effects to these species are generally considered "significant" except where substantial new data may show otherwise, as, in this case, it does for chaparral sand-verbena.

Listed Threatened or Endangered Plant Species

Staff's review of available survey information and other literature sources indicates that no State or federally listed threatened or endangered plants have the potential to occur within the solar generator site or generator tie-line corridor (see **Biological Resources Table 4**, Special-Status Species, Their Status, and Potential Occurrence at the Rice Solar Energy Project Site, above). Potential for occurrence of any listed threatened or endangered plants along the existing 161 kV Western Parker-Blythe #2 transmission line is unknown.

CNPS List 1B/BLM Sensitive Plant Species

One CNPS List 1B and BLM Sensitive species (chaparral sand-verbena) was documented on the project site during field surveys in March 2009. The plants were not present later in the spring when botanists returned to confirm the species identification. Instead, the identification of the chaparral sand-verbena plants on the site is inferred from confirmed identification of another, off-site population (Appendix 5.2.B of SR 2009a). Due to the plant's local distribution and abundance in the Colorado Desert, well outside the area where chaparral sand-verbena is considered rare, staff concludes that this plant is not regionally rare and that impacts would not be significant (see **Special-Status Plants**, above).

There is a low probability that one or more additional CNPS List 1B/BLM Sensitive plant species could occur on the project site (e.g., Orocopia sage). The applicant is currently conducting follow-up surveys to evaluate potential occurrence of later-flowering special-status plants on the solar generator site and generator tie-line alignment. Potential for occurrence of any CNPS List 1B plants along the existing 161 kV Western Parker-Blythe #2 transmission line is unknown.

CNPS List 2 Plant Species

One CNPS List 2 species (Harwood's milk-vetch) was documented on the generator tie-line alignment during field surveys in March 2009 (SR 2009a). Staff concludes that project impacts to this species would meet CEQA criteria as significant and recommends Condition of Certification **BIO-12** (Special-Status Plant Impact Avoidance and Minimization) to mitigate this impact below a level of significance.

This Condition of Certification would require the project owner to complete pre-construction field surveys of the generator tie-line alignment to identify and map any special-status plants occurring there, to the extent feasible; to designate these locations as Special-Status Plant Protection Areas; and to design and plan for tie-line construction to avoid impacts to these areas (e.g., transmission line tower locations, pull sites, and other disturbance). The project owner would be required to prepare and implement a Special-Status Plant Protection and Monitoring Plan to ensure protection of these sites. Where special-status plant occurrences cannot be feasibly avoided, the project owner would be required to prepare and implement a Special-Status Plant Remedial Action Plan to provide detailed species-specific replacement mitigation, to consist of seed collection and storage, and species reintroduction into suitable habitat.

In addition to Harwood's milk-vetch, there is a low to moderate probability that any of several additional CNPS List 2 plant species that can only be found during late summer or fall due to their growing season could occur on the solar generator site and generator tie-line alignment (see **Biological Resources Table 4**, Special-Status Species, Their Status, and Potential Occurrence at the Rice Solar Energy Project Site, above). Staff's recommended Condition of Certification **BIO-12** would require late-season botanical surveys to determine likelihood that any of these plants could occur on the site. Potential for occurrence of any CNPS List 2 plants along the existing 161 kV Western Parker-Blythe #2 transmission line is unknown.

CNPS List 3 Plant Species

Plant species included in CNPS List 3 are those species for which further information is needed to evaluate their appropriate conservation status. Nearly all of these species are "taxonomically problematic" (CNPS 2001). These plants may meet CEQA significance criteria in some circumstances and they should be evaluated in a CEQA analysis. One CNPS List 3 species, Wiggins' cholla, is reported in the AFC Appendix 5.2C, Desert Tortoise Survey Report, though the plant may have been misidentified or may have been recorded off-site, on desert tortoise zone of influence transects. Based on current taxonomic understanding, Wiggins' cholla appears not to be a valid taxon (see **Special-Status Plants**, above). Because recent taxonomic treatments do not recognize Wiggins' cholla as a valid subspecies, staff concludes that project impacts to Wiggins' cholla, if they were to occur, would not reach the Energy Commission's adopted threshold of significance. No other CNPS List 3 plants are likely to occur on the solar generator site or generator tie-line alignment (see **Biological Resources Table 4**, Special-Status Species, Their Status, and Potential Occurrence at the Rice Solar Energy Project Site, above). Potential for occurrence of any CNPS List 3 plants along the existing Parker-Blythe #2 transmission line is unknown.

CNPS List 4 Plant Species

Species included on CNPS List 4 are plants of limited distribution or infrequent throughout a broader area of California, and their vulnerability or susceptibility to threat appears low at this time (CNPS 2010). Very few CNPS List 4 plants meet the definition for state or federal listing (CNPS 2001). Nevertheless, they may be locally significant if, for example, they occur at the periphery of their geographic range, exhibit unusual morphology, or occur in atypical habitats. Thus, they should be evaluated in a CEQA analysis.

One CNPS List 4 species, Utah cynanchum, is reported in Appendix 5.2C (Desert Tortoise Survey Report) of the AFC, though the plant may have been misidentified or may have been recorded off-site, on desert tortoise zone of influence transects (see **Special-Status Plants**, above). Utah cynanchum has not been observed or reported on the site by the applicant's botanical consultant. However, the site is within its geographic range (Bell 2009), and suitable desert wash habitat may be present in desert washes on the proposed generator tie-line alignment. Based on its known geographic range and abundance, absence of any reported unusual morphology among local populations, and local occurrence in typical habitat, staff concludes that project impacts to Utah cynanchum potentially occurring on the generator tie-line alignment would not reach the level of significance under the Energy Commission's adopted significance criteria.

There is a low to moderate probability that any of several additional CNPS List 4 plant species that can only be found during late summer or fall due to their growing season could occur on the solar generator site or generator tie-line alignment (see **Biological Resources Table 4**, Special-Status Species, Their Status, and Potential Occurrence at the Rice Solar Energy Project Site, above). Staff's recommended Condition of Certification **BIO-12** would require late-season botanical surveys to determine likelihood that any of these plants could occur on the site. Potential for occurrence of any CNPS List 4 plants along the existing 161 kV Western Parker-Blythe #2 transmission line is unknown.

Special Status Plant Species Impact Evaluation and Mitigation Strategy

Staff concludes that project impacts to Harwood's milk-vetch would reach CEQA standards as significant, and that several other species not documented on the site also could occur there and, if present, could also be subject to adverse and potentially significant project impacts. The extent of these impacts cannot be fully evaluated due to limitations of available field survey data. Staff recommends an impact evaluation and mitigation strategy that would fully evaluate potential project impacts to special-status plants and mitigate any significant impacts below a level of significance.

Staff evaluated several approaches to mitigating these impacts. These approaches were:

1. Avoiding or minimizing direct impacts.
2. Acquisition and protection of special-status plant populations on private lands.
3. Protection and enhancement of populations on public lands.
4. Seed collection, translocation or transplantation of special-status plants.

Mitigation Strategies Considered But Rejected

Protection and Enhancement of Populations on Public Lands. Special-status plant occurrences on National Park Service lands are considered to be adequately protected and thus offer no potential for offsetting project losses. In recognition that some of the occurrences on BLM land are subject to the effects of grazing, ORV, transmission projects, mining (CDFG 2010a), and future energy projects, staff investigated the possibility of off-setting project losses by placing land use restrictions on or enhancing

BLM lands where one or more of these special-status plants occur and which are not protected, such as within a Desert Wildlife Management Area (DWMA). However, BLM cannot make pre-decisional commitments to implement specific actions such as fencing, altering grazing allotments, burro removal, or habitat restoration without conducting NEPA analysis and providing full public disclosure on the effects of those actions. Thus, mitigation measures such as land use changes potentially affecting other uses would necessitate a separate NEPA analysis. Consequently, this mitigation option would not be timely and its outcome would remain unknown until BLM completed a Record of Decision. Pursuant to CEQA and NEPA, the Energy Commission and Western cannot defer mitigation to a future NEPA document.

Transplantation or Translocation (including re-seeding). The applicant has proposed collecting seed and reseeded special status plants at an offsite location as a potential mitigation strategy (SR 1998a). However, the general consensus in the scientific community is that transplantation or re-seeding have not been shown to be viable strategies for special-status plant mitigation (Howald 1996). A study by CDFG (Fiedler 1991) found that, even under optimum conditions, transplantation was not effective in 85% of cases studied. Nonetheless for some species including cacti transplanting is often a statutory requirement. On BLM lands, all yucca species and most cacti, with the exception of chollas, must be salvaged and transplanted. It is CNPS's (1998) policy to oppose transplantation as mitigation for loss of rare plants. In a separate policy statement, CNPS (1992) identifies appropriate use of ex-situ conservation techniques and summarizes reasons these techniques have failed as mitigation.

Successful translocation or transplantation requires extensive information about microhabitat requirements, reproductive biology, essential pollinators, soil conditions and soil organisms, community relationships, and other critical biological characteristics. This information is lacking for most species, including the special-status species that would be affected by the proposed project. In consideration of the high rate of failed transplantation and translocation attempts with rare plants, staff believes that translocation would not provide meaningful conservation benefit, unless proven species-specific feasible methods are specified and adhered to with rigorous performance monitoring. Staff knows of no such methods for Harwood's milk-vetch or other special status species potentially occurring on the solar generator site, the generator tie-line alignment, or the existing 161 kV Parker-Blythe #2 transmission line. In the absence of known and proven reestablishment techniques for a given species, reestablishment attempts must be considered experimental in nature. These efforts may show early promise but lose viability or decline after the first few years due to one or more of the many factors listed above. Staff concludes that experimental reintroductions could yield important new information that may inform future mitigation efforts, but cannot be expected to succeed and therefore would not constitute mitigation as it is defined under CEQA.

Seed collection as long-term germplasm preservation. The applicant has proposed collecting seed for donation to botanical gardens or universities for propagation and study (SR 1998a). Staff agrees that seed collection for this purpose is a useful and important component of mitigation, and staff recommends long-term germplasm conservation as a part of the special status plant mitigation strategy in Condition of

Certification **BIO-12**. However, for most rare plants that could be impacted by the project, seed collection alone would not mitigate impacts below a level of significance.

In lieu fee. The applicant proposes *in lieu* fee payment as a potential mitigation measure for rare plants (SR 2009a) The overall approach to compensatory mitigation for desert tortoise habitat loss on this and other proposed solar projects has not yet been resolved by land management and resource agencies. Current BLM policy allows for *in lieu* fee payment as an alternative to purchasing and protecting private lands. *In lieu* mitigation fees for this and other proposed projects would be pooled and dedicated to purchasing and managing desert tortoise mitigation lands. Newly developing State policy would likely create similar mitigation fees for compensatory lands.

In lieu fee payment to fund compensatory mitigation for desert tortoise habitat loss would not feasibly or verifiably mitigate the project's impacts to special-status plants, unless the presence of special-status plants affected by the project are verified on the land planned for acquisition and protection and management of the plants is assured and funded in perpetuity. The *in lieu* fee program was not sufficiently developed at the time the SA/DEIS was prepared to judge whether it will be able to accommodate mitigation for special-status plants as part of the desert tortoise habitat mitigation. Under limited circumstances, compensation lands for desert tortoise could, however, serve to mitigate adverse impacts to rare plants, as discussed below and in staff's recommended Condition of Certification **BIO-12**.

Staff's Recommended Conceptual Mitigation Strategy

To reduce project impacts to CNPS List 1 and List 2 plants below a level of significance, staff recommends a mitigation strategy to (1) avoid Harwood's milk-vetch locations on the generator tie-line alignment, (2) determine whether any additional late-season special-status plants occur on the solar generator site or generator tie-line alignment or would be affected by the project, (3) determine whether any special-status plants occur on the existing 161-kV Parker-Blythe transmission line, and (4) identify and mitigate any additional significant adverse impacts to most CNPS List 1B and List 2 plants through avoidance measures, by protecting acquired lands off-site, or through other off-site measures such as habitat improvement or management. Staff recommends mitigation for any additional CNPS List 1A, 1B, or List 2 plants discovered within the project area or within 250 feet of any project activities during future pre-construction clearance surveys as recommended in staff's proposed Condition of Certification **BIO-12**. This mitigation strategy is described further in the paragraphs below. Full implementation of this mitigation strategy would reduce the project's direct, indirect, and cumulative impacts below a level of significance by locating CNPS List 1 and List 2 plants that may be affected by the project, and mitigating any significant adverse impacts to them through avoidance and protection, or through acquiring and protecting lands off-site, or through other off-site measures such as habitat improvement or management. Staff concludes that this mitigation strategy is both feasible and effective.

Avoiding or minimizing direct impacts. Staff's recommended mitigation approach is to avoid or minimize any construction impacts to Harwood's milk-vetch or most other CNPS List 1 or List 2 plant locations on the solar generator site, the generator tie-line alignment or the existing 161-kV Parker-Blythe #2 transmission line. Protection would be achieved by avoiding direct and indirect impacts to the plants and a 250-foot buffer

area surrounding each protected plant location. Staff concludes that this goal is feasible and would reduce impacts to Harwood's milk-vetch below a level of significance.

This level of protection is not recommended for chaparral sand-verbena because staff concludes that impacts to this plant would be less than significant under CEQA.

Staff's proposed Condition of Certification **BIO-12** (Special-Status Plant Impact Avoidance and Minimization) requires the applicant to minimize disturbance to the extent feasible as described above. This condition also requires preparation of a special-status plant protection and monitoring plan to be implemented for the life of the project and other measures to fully avoid impacts to Harwood's milk-vetch and any additional CNPS List 1 or List 2 taxa discovered during future botanical field surveys.

Additional Field Surveys. Due to the potential for occurrence of special-status late-season plant taxa on the project site, staff recommends follow-up late-season field surveys in summer and fall 2010. Staff's proposed Condition of Certification **BIO-12, Section B** describes scheduling and other recommendations for these additional surveys; **Section C** describes thresholds for identifying significant impacts to special status plants that may be found during those surveys; and **Section D** would require that the project owner prepare and implement a mitigation plan for any such impacts. **Section D** also describes a series of potential mitigation strategies that would reduce these impacts below a level of significance.

Conclusion: Summary of Special-Status Plant Impacts and Mitigation

Staff has concluded that implementation of proposed Conditions of Certification **BIO-1** through **BIO-12** would be effective and feasible in reducing impacts to special-status plants at the solar generator site, generator tie-line alignment, and interconnector substation to less-than-significant levels. Proposed Condition of Certification **BIO-12** would require late-season field surveys to document presently unknown locations of other special-status plants; provides specific thresholds to determine whether impacts to newly discovered plants would be significant; and would require additional mitigation to reduce such impacts below a level of significance. Staff has not determined potential significance of project impacts along Western existing Parker-Blythe #2 Transmission Line.

Indirect and Off-Site Construction Impacts to Vegetation, Habitat, and Special-Status Plants

Project construction has the potential to cause a variety of indirect effects to vegetation, habitat, and special-status plants outside the project boundary (including areas outside transmission line construction area boundaries). These include effects of erosion or sedimentation that could result from altered hydrology on the site (i.e., plants, their habitat, or their seed banks occurring down slope of disturbed soils could be eroded away or could be covered in sediment); changes in the hydrology from alterations in the drainage patterns of the site (sensitive habitat types and several special-status plant species are associated with desert washes); the introduction of new weeds or spread of weeds already present in the area from the solar fields into the surrounding habitat; greater than normal dust levels; effects of herbicide drift on special-status plants,

vegetation, and pollinators; and an increased risk of fire. Weeds and dust are discussed above, and hydrology is discussed below.

The Conservation Biology Institute (CBI 2000) reviewed a variety of edge effects known or likely to adversely affect a rare plant species in southern California, and evaluated buffer distances in terms of their potential to prevent those effects. The CBI review evaluated edge effects expected to result from suburban development in interior Ventura County. Staff is not aware of any available research that would be more applicable to the RSEP. CBI reviewed potential effects of invasive plant and animal species; vegetation management (e.g., for fuels management); trampling; increased water supply (e.g., irrigation runoff); chemicals such as pesticides, herbicides, and fertilizers; and increased fire frequency. These edge effects are largely comparable to expected edge effects that would result from the RSEP. For example, soil disturbance and altered shade and hydrology on the solar generator site will likely lead to weed invasions (described above), which could spread from the site into surrounding desert. Construction-related soil disturbance along linear project facilities would have similar effects. Watering for dust control or other project-related hydrology changes could cause colonization by invasive ant species which, in turn, could affect specialized habitat conditions in surrounding soils. CBI concluded that buffer distances of 200-300 feet were “moderately” or “highly” likely to be effective in minimizing these adverse edge effects on rare plant habitat. Based on CBI’s analysis, staff concludes that the project would likely cause adverse indirect effects to any rare plant occurrences within a 250-foot radius of project activities. Therefore, staff’s proposed Condition of Certification **BIO-12** (Special-Status Plant Impact Avoidance and Minimization) requires pre-construction surveys within the 250-foot buffer beyond anticipated limits of grading at each transmission line construction site, including the interconnection substation site, and requires avoiding project activities or mitigating impacts to any protected plant occurrences at those sites.

Construction Impacts to Common Wildlife and Habitat

Construction of the proposed RSEP, including the solar generation and generator tie-line, would result in direct and indirect impacts to common wildlife species (i.e., species without special-status designation) and their habitat. These effects could include mortality of small mammals, reptiles, the eggs or nestlings of shrubland birds, and other less mobile species from trampling or crushing during clearing, grading, or excavation; and increased predation when wildlife is flushed from cover during site clearing or rendered vulnerable to predation due to increased disturbance by construction noise or lighting.

In addition to mortality, project construction would cause wildlife displacement from the project site and surrounding habitat due to loss of habitat, increased vehicular and human presence throughout the site, increased fugitive dust, noise and lighting disturbances, and a modified hydrologic and sediment regime due to the construction of the storm water management system. Mobile species such as adult birds would generally disperse into nearby habitat areas during construction (impacts to nesting birds are discussed in more detail below under **Impacts to Common Migratory and Resident Birds**). However, mammals and reptiles would be hindered or prevented from

escaping the construction site by the project's perimeter fencing (i.e., the desert tortoise exclusion fence, described further below).

Animals dispersing from the construction site still would be subject to adverse effects, potentially including mortality, after leaving the site. After leaving their home territories, they may be unable to find suitable food or cover in new, unfamiliar areas. Or, if they find food and other resources, these may be within the occupied territory of another individual of the same or similar species, and would result in competition for resources. The energy and time spent on competition would likely cause reduced vigor, at least temporarily, perhaps making the animals vulnerable to predation or physical demands during migration, and potentially reducing or precluding reproduction.

Construction disturbance such as noise, lighting, dust, invasive weeds, and increased human activity are likely to discourage wildlife from foraging and nesting adjacent to the proposed project throughout the construction phase of its implementation. Dust and invasive weeds are discussed in more detail above under **Impacts to Vegetation**. Lighting is discussed further under **Impacts During Operation** below. Noise during operation is also discussed in that section. According to data presented in the AFC (SR 2009a), noise generated by various construction activities is expected to range between 85 and 98 dBA on the site. These levels attenuate to less than about 50 dBA at distances of one mile. The loudest single noise events during project construction would be "steam blows," to clean scale and debris from boiler tubes. These reach a level of 110 dBA at 1000 ft. from the source (i.e., the power block, in the center of the heliostat field) (SR 2009a). The noise levels of these tests would attenuate considerably at the perimeter fence (approximately 3,200 to 5,000 feet from the power block) but levels at the heliostat field perimeter are not stated in the AFC. Construction noise effects on wildlife in the surrounding area will vary, depending on distance from the noise source; time of day, and persistence of the noise. Noise could affect wildlife in adjacent habitats by disrupting foraging, breeding, sheltering, and other activities; or it could cause animals to avoid otherwise suitable habitat surrounding the site. The effects of construction noise include annoyance, which causes birds and other wildlife to abandon nests or dens; increased stress hormone levels, interference with sleep and other activities; and interference with acoustic communication by masking important sounds or sound components, such as territorial calls, contact calls, or alarm calls (Dooling 2006). Many species rely on vocalizations during the breeding season to attract a mate within their territory, and noise from construction could disturb nesting birds and other wildlife and adversely affect nesting and other activities. Reijnen et al. (1995) demonstrated that for two species of European warbler (*Phylloscopus* spp.), sound levels between 26 dB(A) and 40 dB(A) reduced breeding density by up to 60 percent compared to undisturbed areas. These data suggest project-related construction disturbance would reduce wildlife habitat use or breeding success adjacent to disturbance.

Construction effects on nocturnal (i.e., active at night) wildlife would be dependent upon construction schedules. Although noise would likely be important overnight, increased lighting (including security lighting) would likely affect some species.

Prior to construction, the project site would be enclosed within a desert tortoise exclusion fence, and tortoises inhabiting the project site would be removed from the

enclosure area (see **Impacts to Desert Tortoise** below). Once in place, this enclosure fence would entrap most mammal and reptile wildlife species within the project site. These animals, if they persist within the project area, would be subject to disturbance and habitat loss during construction and to ongoing, repeated disturbance during project operation. While many species can tolerate human disturbance to some degree, the project's construction and operation would cause ongoing habitat degradation and loss of wildlife, primarily due to habitat alteration and mortality on access and maintenance roads within the site.

Construction-related effects to common wildlife typically are not considered significant under CEQA. However, the large scale of the project site, the fact that animals would remain trapped within the perimeter fencing, and the multiyear construction schedule would result in potential significant effects to common species. To reduce these impacts, staff recommends several Conditions of Certification, listed below. These conditions would educate workers of the presence and sensitivity of wildlife that may occur in the project area, provide limitations on work that may occur during the breeding season, reduce the effect of fugitive dust on adjacent areas through dust control and reduced vehicle speeds, require monitoring of construction to reduce direct wildlife mortality, and the control of weeds.

Implementation of staff's proposed Conditions of Certification **BIO-1** through **BIO-11** would minimize potential impacts to common wildlife. In combination with Condition of Certification **BIO-16**, which would require compensatory land acquisition to mitigate impacts to desert tortoise (described below), these measures would mitigate impacts to common wildlife at the solar generator site, generator tie-line alignment, and interconnector substation to less-than-significant levels. Staff has not determined potential significance of project impacts along Western existing Parker-Blythe #2 Transmission Line.

Construction Impacts to Common Migratory and Resident Birds

General impacts such as habitat loss, noise, lighting, and human disturbances to common wildlife, including most birds, are described above (**Impacts to Common Wildlife**). This subsection focuses on impacts to bird species regulated under state and federal statute. The federal Migratory Bird Treaty Act (MBTA) prohibits take of any migratory bird as defined in the Act (or any part of such migratory bird including active nests) except as permitted by regulation (e.g., duck hunting). Under the MBTA, "migratory bird" is broadly defined as "any species or family of birds that live, reproduce or migrate within or across international borders at some point during their annual life cycle" and thus applies to most native bird species. California Fish and Game Code Section 3503 prohibits take, possession, or needless destruction of bird nests or eggs; Section 3503.5 prohibits take or possession of birds of prey or their eggs; and Section 3513 prohibits take or possession of any migratory nongame bird. With the exception of a few non-native birds such as European starling, the take of any birds or loss of active bird nests or young is regulated by these statutes. Most of these species have no other special conservation status as defined above (**Biological Resources Table 4**).

Potential construction-related project impacts discussed here would generally apply to all bird species, including special-status birds. Additional project impacts to all birds that would likely occur during operation of the proposed RSEP facility, including mortality

caused by striking the heliostats, central tower, or flying through focused solar energy points, are addressed below (**Impacts During Operation**). The project also could have more specific impacts to special-status birds, dependent on the behavior, seasonality, and habitat requirements of each species. These are discussed in more detail below (**Impacts to Special-Status Birds**).

The entire project site and surrounding area, including the proposed generator tie-line, provides suitable nesting habitat for numerous resident and migratory bird species. Examples of species likely to nest in shrubs or on the ground on the RSEP site and observed during desert tortoise surveys (Appendix 5.2C of SR 2009a) include northern mockingbird, white-winged dove, lesser nighthawk, common poorwill, and horned lark. The Lower Colorado River Valley supports some 60 year-round resident bird species, 28 breeding season migrants, and 80 winter migrants (Rosenberg et al. 1991). About half of these birds are found in wetland or riparian habitats and thus would not be expected on the proposed RSEP solar generator site or the generator tie-line alignment. These species may occur in portions of the Western's existing 161-kV Parker-Blythe #2 transmission line and may also migrate seasonally through the Rice Valley where they may be subject to project-related construction disturbance. The project site could provide seasonal or year-round habitat for dozens of native bird species. Most of these birds have no special conservation status, and adverse impacts generally would not warrant a finding of significant impacts under CEQA. However, they all are protected under the MBTA and Fish and Game Code Sections 3503 and 3513 as described above.

Many adult birds would flee from equipment during initial vegetation clearance for project construction. However, nestlings and eggs would be vulnerable to impacts during project construction, and are also protected by the MBTA and Fish and Game Code Sections 3503 and 3513. If initial site grading or brush removal were to occur during nesting season, then it likely would destroy bird nests, including eggs or nestling birds. One special-status species, the burrowing owl, is unlikely to flee the site during construction, due to its characteristic behavior of taking cover in burrows. Potential project impacts and an avoidance and mitigation strategy for burrowing owl are provided below (**Impacts to Special-Status Birds**).

The applicant has proposed mitigation measures to avoid and minimize impacts to nesting birds that have been incorporated into staff's proposed Condition of Certification **BIO-13** (Pre-Construction Nest Surveys and Impact Avoidance Measures for Migratory Birds). This measure includes removing vegetation outside the breeding season, pre-construction nesting surveys, and the establishment of 500-foot buffers around active nests for most birds (1,200 feet for active raptor nests). The applicant also notes that biological monitors and project personnel will need to be diligent in identifying any nest-building behavior on the construction site before birds lay eggs. Staff concurs with the approach proposed by the applicant but considers it difficult to achieve due to the extended construction schedule and the numerous common birds with potential to nest within the area prior to and during construction.

Some species of birds will likely nest in the project area during construction and operation of the facility. Depending on the species, birds may nest on the ground close to equipment, within the open metal framework of the heliostat structures, on buildings

or other structures, or on idle construction equipment. For example, staff has observed recent nesting activity at several large electrical transmission line projects currently underway in the western Mojave Desert. In these locations birds have nested on vehicles, foundations, construction trailers, and other equipment left overnight or during a long weekend. In areas where construction was phased (i.e., footings, or tower structures) birds quickly utilized these features as nest sites. Most of these nesting birds were common ravens, house finches, and mourning doves, all of which are protected by the MBTA and Fish and Game Code Sections 3503 and 3513. Staff considers that the likelihood of encountering nesting birds on-site during construction, within the 500-foot disturbance buffer proposed by the applicant, or on vehicles and equipment would be high. Therefore, staff recommends that to avoid impacts to nesting birds, preconstruction surveys and regular monitoring of the work area shall be conducted at any time work is to occur during the breeding season. If active nests are detected during the surveys or monitoring, a 500-foot disturbance-free buffer zone shall be implemented (Condition of Certification **BIO-13**, Pre-Construction Nest Surveys and Impact Avoidance Measures for Migratory Birds). Implementation of staff's proposed conditions of certification would avoid direct impacts (including take) to migratory birds and their nests, eggs, or young and would reduce the impacts of construction disturbance at the solar generator site, generator tie-line alignment, interconnector substation and on the existing 161 kV Parker-Blythe #2 Transmission Line to nesting birds to less-than-significant levels under CEQA. Potential project impacts to special status birds are described in more detail below and, in some cases, staff recommends additional mitigation measures, or does not determine potential significance of project impacts along Western existing Parker-Blythe #2 Transmission Line.

Even with pre-construction surveys, monitoring, and other measures, the scale of the project and the known nesting behaviors of some native birds increases the likelihood that the project would require the removal or relocation of active nests in order to proceed with construction or operate the facility. To comply with the legal requirements under the MBTA and California Fish and Game Code, staff has proposed as part of Condition of Certification **BIO-13** that the applicant coordinate with staff, CDFG, and USFWS to be certain that any removal and relocation work is conducted properly. Similarly, staff has provided language in proposed Condition of Certification **BIO-13** that would allow certain construction activities to occur closer than 500 feet to active nests with approval of staff, CDFG, and USFWS. The ability to work closer than the proposed 500-foot (1,200 feet for raptors) buffer would depend on the species, stage of development of chicks within the nest, proposed construction activity, and biological response of the animal.

Construction Impacts to Special-Status Wildlife

Habitat in the proposed RSEP solar generation site and generator tie-line alignment has the potential to support a variety of special-status wildlife including State and federally listed species. The special-status species observed within or near these project components include desert tortoise, Mojave fringe-toed lizard, loggerhead shrike, prairie falcon, burrowing owl, and desert kit fox. In addition, golden eagle, while not observed on the site, is likely to forage in the area and is fully protected under the California Fish and Game Code and federal Bald and Golden Eagle Act. **Biological Resource Table 4** describes these and other special-status species that have the potential to occur in the

project area. In addition, construction of the proposed fiber optic OPGW along Western's existing 161-kV Parker-Blythe #2 transmission line could impact species or habitats not described here.

Impacts to special-status species, including listed species, would generally be similar to those described above for common wildlife and could be caused by a variety of direct and indirect factors. Direct impacts to wildlife could include displacement and/or potential mortality of wildlife that are poor dispersers such as tortoise, lizards, and small mammals. Construction may also cause the temporary degradation of the value of adjacent native habitat areas due to disturbance, noise, increased human presence, and increased vehicle traffic during construction. Long-term indirect impacts may include increased human presence and the loss of habitat through the colonization of non-native invasive plants. Mortality or loss of reproductive success may also occur during land clearing, excavation, grading, and construction of the RSEP. Potential project impacts to special-status species are detailed below.

Cheeseweed Owlfly

Cheeseweed owlfly is known from an occurrence along the proposed generator tie-line corridor. Creosote bush shrubland throughout the RSEP and generator tie-line alignment is apparently suitable habitat, though its distance from local hilltop sites and the effects of soil compaction from previous land uses may reduce its suitability. The project area does not appear to provide specialized habitat or other resources for cheeseweed owlfly other than those resources widely available throughout the region. Project development would result in the loss of potentially suitable habitat throughout the proposed solar generation site and adjacent temporary construction site; and additional habitat loss, including some historically occupied habitat, for access road and transmission line construction along the proposed generator tie-line alignment. Additional suitable habitat may also be affected along Western's existing 161-kV Parker-Blythe #2 transmission line.

Cheeseweed owlfly has a conservation ranking with the CDFG Natural Diversity Database of S1S3, indicating uncertain status ranging between "critically imperiled" and "vulnerable" (CDFG 2009b). Based on the known historic occurrence on the generator tie-line alignment, the RSEP's proposed disturbance to a large area of potentially suitable habitat, and the uncertain conservation status, staff concludes that project impacts to cheeseweed owlfly would be significant under CEQA.

Implementation of staff's proposed Conditions of Certification **BIO-1** through **BIO-10** would minimize potential impacts to cheeseweed owlfly and its habitat. Staff concludes that implementation of these measures would reduce potential project impacts to less than significant because they would require minimization of habitat disturbance in the area of known historic occurrence and throughout the project area to only that area required for construction; revegetation of disturbed areas along linear project components after construction, and other measures to minimize impacts. In addition, Condition of Certification **BIO-16** would require compensatory land acquisition to mitigate impacts to desert tortoise (described below); staff believes that protection of these compensatory lands would be likely to protect habitat for cheeseweed owlfly. Staff

concludes that no additional mitigation is required to reduce potential impacts to cheeseweed owlly below a level of significance.

Couch's Spadefoot

The solar generator site is near the western margin of Couch's spadefoot's geographic range, and much of Western's existing 161-kV Parker-Blythe #2 transmission line are within its known range. There are several known regional occurrences (Jennings and Hayes 1995; Morey 2005). Drainage channels and topography on the proposed solar generation site and along the proposed generator tie-line alignment indicated that no suitable breeding pools would form or hold rain water long enough for spadefoot reproduction (Attachment DR60-1 of CH2MHill 2010a). Habitat suitability along the Parker-Blythe #2 transmission line is unknown. Creosote bush shrubland throughout the RSEP and its linear project components may be suitable as habitat for winter dormancy within burrows. Based on anecdotal information on a number of species, Hammerson (2002) reported that spadefoots move several hundred meters or more from breeding sites and suggested that, without specific information, the minimum extent of terrestrial habitat around breeding sites can be set at 500 meters. A further evaluation of habitat suitability would require more detailed knowledge of Couch's spadefoot movement distances between breeding ponds and burrow sites. Further, the effects of soil compaction from previous land uses may reduce habitat suitability on the RSEP site. The solar generator site and generator tie-line alignment do not appear to provide specialized habitat or other resources for Couch's spadefoot other than those resources widely available throughout the region; however, available information cannot rule out the potential that Couch's spadefoot could overwinter on the site.

RSEP development would result in loss of potentially suitable habitat throughout part or all of the proposed solar generation site, adjacent temporary construction site, and interconnector substation site. Suitable habitat on the generator tie-line and Western's existing 161-kV Parker-Blythe #2 transmission line could also be temporarily or permanently lost during construction. In addition to habitat loss, project construction could destroy individual Couch's spadefoots if breeding ponds are disrupted while adults, eggs, tadpoles, or juvenile spadefoots are present, or if the animals are crushed in their burrows by vehicle traffic.

In California, Couch's spadefoot is threatened by habitat conversion for other uses. It is ranked as a Species of Special Concern by CDFG and as a Sensitive Species by BLM. Although potential occurrence on the site is unknown, particularly on Western's existing 161-kV Parker-Blythe #2 transmission line, because of the RSEP's proposed disturbance to a large area of potentially suitable burrowing/winter dormancy habitat, staff concludes that project impacts to Couch's spadefoot, if it occurs in the area, would be significant under CEQA. Staff notes, however, that long-term or permanent habitat loss along the project's transmission line components would be minimal, and that impacts of these project components would primarily be those resulting from short-term construction.

Implementation of staff's proposed Conditions of Certification **BIO-1** through **BIO-10** would minimize potential impacts to Couch's spadefoot and its habitat. In addition, staff recommends **Condition of Certification BIO- 23** (Couch's Spadefoot Surveys and

Breeding Habitat Avoidance) which would require preconstruction surveys for potential habitat along project transmission line alignments and seasonal avoidance of that habitat during construction. Staff concludes that implementation of these measures would reduce potential project impacts to Couch's spadefoot to less than significant at the solar generator site, generator tie-line alignment, interconnector substation and along Western existing Parker-Blythe #2 Transmission Line because they would require minimization of habitat disturbance to only that area required for construction; and seasonal avoidance of impacts to breeding habitat. Staff concludes that no additional mitigation is required to reduce potential impacts to Couch's spadefoot below a level of significance.

Mojave Fringe-Toed Lizard

The proposed solar generator site does not appear to provide suitable habitat for Mojave fringe-toed lizard, except perhaps very marginal habitat within sandy washes that cross the site from north to south, though portions of the generator tie-line alignment provide suitable habitat (Black 2010; CH2MHill 2010h). The Danby Dunes, which are occupied Mojave fringe-toed lizard habitat, are located off-site to the south. There is a known occurrence about 0.75 mi south (SR 2009a) and patches of sparsely vegetated sand dunes are located within approximately 1,000 feet south of the southern proposed RSEP solar generation site boundary (Appendix A). It is likely that individual Mojave fringe-toed lizards occur throughout the Danby Dunes and adjacent sparsely vegetated dunes. It also is likely that individual animals infrequently travel northward among scattered or partially stabilized sandfields and along the sandy washes from the occupied habitat to the proposed RSEP site.

If the solar generator site were located between two areas of suitable habitat, then these washes could serve as dispersal routes for animals moving between the two areas. Instead, however, there is no potential Mojave fringe-toed lizard habitat upslope, and the washes on-site offer no opportunity for dispersal between the Danby Dunes and suitable habitat elsewhere in the area.

It is possible, but unlikely, that individual Mojave fringe-toed lizards could wander from the Danby Dunes onto the solar generator site where they could be crushed during construction or adversely affected by other aspects of the project. Although the species is ranked by CDFG as a Species of Special Concern and by BLM as a Sensitive Species, staff concludes that these impacts, should they occur, would be less than significant under CEQA.

Because the project site is located upslope from the Danby Dunes, the proposed solar facility has the potential to interrupt fluvial or aeolian sand transport to the Danby Dunes from upslope or upwind sources. These potential effects were evaluated and found to be less than significant (Appendix A). The proposed RSEP solar generation site is outside the wind corridor that transports sand to the dunes. Fluvial sand transport during infrequent flash floods would largely continue without significant interruption, via the existing desert washes and proposed new drainage channels at the northern boundaries of the proposed solar generation site. Sand originating from the heliostat field contributes only minimally to the Danby Dunes and interruption of that source would not be significant.

Suitable aeolian sand habitat or fine sandy desert wash habitat that may be occupied by Mojave fringe-toed lizards may occur in patches along the proposed generator tie-line alignment, at the interconnector substation site, or on Western's existing 161-kV Parker-Blythe transmission line. Project-related transmission line construction and upgrades would temporarily disturb habitat, and could crush individual Mojave fringe-toed lizards. But habitat for these animals, consisting of open sand, is expected to recover quickly following disturbance because vegetation recovery is not required. Thus, habitat impacts would be short-term. Staff concludes that, without avoidance or mitigation, potential take of individual Mojave fringe-toed lizards for transmission line work could be significant under CEQA, but habitat impacts would not be significant.

In Response to Data Request 51 (CH2MHill 2010a), the applicant notes that mitigation measures may be necessary to avoid and protect these areas during generator tie-line construction, and suggests that "judicious placement of generator tie-line towers may lead to avoidance of such habitats" and that "a plan to avoid impacts during construction by fencing and monitoring these areas would be appropriate." Staff concurs with the applicant's suggestion, and recommends Conditions of Certification **BIO-1** through **BIO-10**, which would minimize potential impacts to Mojave fringe-toed lizards and potential habitat, including marginal habitat, during generator tie-line construction or project-related work on the existing Parker-Blythe #2 161-kV transmission line. Proposed Condition of Certification **BIO-8** specifically requires that generator tie-line construction and fiber optic OPGW installation on the existing Parker-Blythe #2 transmission line shall avoid any desert wash, desert microphyll woodland, or any aeolian sand habitat wherever feasible, and that where these sites cannot feasibly be avoided, the Designated Biologist shall outline site-specific requirements to minimize impacts to habitat and wildlife, including Mojave fringe-toed lizard. Staff concludes that implementation of these measures would reduce potential impacts below a level of significance by avoiding construction activities in potential habitat where feasible, and implementing site-specific measures to avoid take of individual animals where habitat avoidance is infeasible.

Gila Monster and Rosy Boa

Neither Gila monsters nor rosy boas were observed during biological surveys conducted in 2009 of the proposed RSEP project site and linear facilities. The site is at the margin of the Gila monster's known geographic range, and the solar generator site does not provide the rocky habitat where both species typically occur. These species may be more likely to occur in surrounding mountains, along the generator tie-line alignment, the existing 161-kV Parker-Blythe #2 transmission line, or at the interconnector substation site. There is only a low potential that the Gila monster may occur in the project area. However, its geographic range is poorly understood and, even in occupied habitat, it occurs in low densities, is difficult to detect, and may be overlooked during surveys. If present, direct impacts could include habitat loss; being hit by vehicles on access roads; and mechanical crushing during site preparation, grading of spur roads, or drainage features. Absent mitigation, staff considers these potential impacts to be significant under CEQA.

Construction of the RSEP would eliminate up to 1,770 acres of marginally suitable habitat that may provide cover, foraging, and breeding habitat for Gila monsters and

rosy boas. The applicant has not proposed specific mitigation to reduce potential impacts to these species. Implementation of staff's proposed Conditions of Certification **BIO-1** through **BIO-10** would minimize impacts to these species and their potential habitat. Condition of Certification **BIO-14** would require capture and relocation of any special-status reptiles encountered during preconstruction desert tortoise clearance surveys (described below). Staff concludes that implementation of these measures would reduce potential project impacts to Gila monster and rosy boa to less than significant because they would require minimization of habitat disturbance to only that area required for construction; and off-site translocation of animals found during preconstruction clearance surveys. Condition of Certification **BIO-16** would require compensatory land acquisition to mitigate impacts to desert tortoise (described below); staff believes that protection of these compensatory lands would be likely to protect habitat for Gila monster and rosy boa. Staff concludes that no additional mitigation is required to reduce potential impacts to these species below a level of significance.

Desert Tortoise

Desert tortoises are present within the proposed RSEP solar field and generator tie-line alignment and the adjacent desert areas surrounding the site. No field survey data are available for Western's existing 161-kV Parker-Blythe #2 transmission line alignment. Information provided by the applicant (SR 2009a) indicated that most of the live desert tortoise occurrences were noted in the zone of influence (ZOI) transects surrounding the solar field site and transmission line. Recent desert tortoise sign was concentrated in the northwest portion of the solar field site and along the southern half of the transmission line route. In the ZOI transects, recent sign was most abundant to the north and west of the solar field site, and along the southern half of the transmission line route. Shell and skeletal remains were found throughout the ZOI transects except in the area south of the solar field site. Juvenile through adult size classes were detected, and egg shell fragments were found at two locations on the solar field site and one location in the ZOI transects. A large number of shell and skeletal remains were found during the surveys, with 71 percent of the remains estimated as greater than four years old at the time of the surveys. The large number of remains suggests that a significantly higher density tortoise population may have been present in the project area and surrounding areas within the last ten years. It is unknown what caused this evidently high level of mortality, but the applicant has speculated that drought and/or disease may be to blame. Currently, the project site and surrounding areas support desert tortoises in low density, but shell fragments on site suggest this population is still reproducing and therefore viable (Appendix 5.2C of SR 2009a). **Biological Resources Table 7** identifies the types and locations of sign observed during protocol surveys conducted April to May 2009. See also Figure 5.2-5 in the AFC and Figures 2 and 3 in Appendix 5.2C of the AFC (SR 2009a).

**Biological Resources Table 7
Desert Tortoise 2009 Protocol Survey Results**

Location	Type of Sign	Quantity	Comments
Solar Field Site (survey area = 2,560 acre project site property boundary)	Live individual	1	
	Shell and skeletal remains	16	13 of the remains were over four years from time of death, 2 were between 2-4 years since time of death, and 1 died within 1 year of the surveys
	Burrow	7	
	Scat	13	All but one scat event less than 1 year old
	Egg shell fragments	2	
	Tracks	1	
Transmission Line Route	Live individual	1	
	Shell and skeletal remains	9	6 of the remains were over four years from time of death and 3 were between 2-4 years since time of death
	Burrow	7	
	Scat	8	All but 2 scat events less than 1 year old
	Egg shell fragments	0	
	Tracks	0	
ZOI Transects (adjacent to project area)	Live individual	5	
	Shell and skeletal remains	66	46 of the remains were over four years from time of death, 15 were between 2-4 years since time of death, 1 was between 1-2 years since time of death, and 1 died within 1 year of the surveys
	Burrow	52	
	Scat	35	All but 11 scat events less than 1 year old
	Egg shell fragments	1	Location of egg shell fragments also a drinking depression
	Tracks	2

Because of the large-scale land use conversion of the solar field site coupled with the expected level of vehicle traffic and maintenance activities (i.e., mowing, mirror washing, etc.) required at the site, construction of the RSEP would require the applicant to translocate any tortoises found within the solar field construction footprint and adjacent diversion channels and logistics and lay-down areas (up to 1,540 acres). Once construction is complete, 1,410 acres would remain fenced to permanently exclude tortoises, to avoid risk of injury or mortality to tortoises during solar generation operations.

One living tortoise was found within the solar generator site. However, the actual number of desert tortoises on the project site cannot be determined from field survey data alone, due to the possibility that some tortoises may have been overlooked during surveys (e.g., they may have been in deep burrows where they could not be seen). The USFWS (2010c: see Table 3) provides a mathematical formula for estimating actual numbers of adult and sub-adult desert tortoises from field survey data. Statistical techniques can provide further estimates of minimum and maximum numbers of tortoises expected, within a 95% confidence interval.

Based on the Service's spreadsheet, two adult or subadult tortoises should be expected on the site, and the number may range from one to as many as 12 (with 95% confidence). In addition, most juvenile tortoises and tortoise eggs are not detected during field surveys. Based on estimates that juveniles account for about 30% to 50% of

a population (Turner et al. 1987), the site would be expected to support a total of about three to four tortoises, including two adults and one or two juveniles.

The number of tortoise eggs expected on the site was estimated based on the assumption of a 1:1 sex ratio and any female tortoise on the site would be expected to lay eggs (clutch) in a given year. Thus, one of the two adult desert tortoises expected onsite is presumed to be a reproductive female. On average, female tortoises produce 1.6 egg clutches per year (Turner et al. 1984), and the average number of eggs per clutch is 5.8 (USFWS 1994). Therefore, staff estimates that 10 eggs would be expected on the site in a typical year. Staff emphasizes that these estimates are extrapolated from field survey data and are not intended to represent the actual numbers of tortoises or eggs on the site.

Survey data provided by the applicant indicates that the generator tie-line alignment and interconnector substation site also are occupied desert tortoise habitat. Staff believes that tortoises or eggs would also be expected along Western's existing 161-kV Parker-Bythe transmission line alignment.

Direct Impacts

Implementation of the project would result in the permanent or long-term loss of approximately 1,770 acres of occupied desert tortoise habitat. The transmission line route would not be fenced and would not pose a barrier to movement for the desert tortoise. The main threat to the desert tortoise related to the transmission line would be risk of injury or mortality during construction or, after construction is complete, vehicle strikes on the approximately 5.4-mile new unpaved access road. The most important impact to desert tortoise would be habitat loss at the solar field site, which would be converted for incompatible land use and fenced to prevent desert tortoises from accessing the site.

During construction of the RSEP, desert tortoises or eggs could be harmed during clearing, grading, and trenching activities or could become entrapped within open trenches and pipes. Construction activities could also cause direct mortality, injury, or harassment of tortoises or eggs as a result of encounters with vehicles or heavy equipment. Other direct effects could include individual tortoises or eggs being crushed or entombed in their burrows, disruption of tortoise behavior during construction or operation of facilities, disturbance by noise or vibrations from the heavy equipment, and injury or mortality from encounters with workers' or visitors' pets. Desert tortoises may also be attracted to the construction area by shade beneath vehicles, equipment, or materials, or the application of water to control dust, placing them at higher risk of injury or mortality. Increased human activity and vehicle travel could disturb, injure, or kill individual tortoises. Also, tortoises may take shelter under parked vehicles where they could be killed, injured, or harassed when the vehicle is moved.

The applicant has recommended impact avoidance and minimization measures to reduce these direct impacts to desert tortoise, including installation of exclusion fencing to keep desert tortoise out of construction areas, translocating the resident desert tortoises from the RSEP site, reducing construction traffic speed limits to reduce the incidence of road kills, and a worker training program. Staff has incorporated these recommendations into conditions of certification. These include Conditions of

Certification **BIO-1** through **BIO-10**, which apply to protection of all biological resources including desert tortoise, and Conditions of Certification **BIO-14** through **BIO-17**, which are specific to desert tortoise.

Staff's proposed Condition of Certification **BIO-14** (Desert Tortoise Clearance Surveys and Exclusion Fencing) would require installation of security and desert tortoise exclusionary fencing around the entire project site and along access roads, and **BIO-15** (Desert Tortoise Translocation Plan) recommends the preparation and implementation of a desert tortoise translocation plan to move any tortoises within the solar generator site to translocation sites, to be determined and identified in the Plan, in coordination with Western, USFWS, BLM, and CDFG. Staff notes that the presence of eggshell fragments on the RSEP site indicate a potential for additional breeding, and that tortoise egg clutches commonly consist of 1 to 12 (often 4 to 6) eggs (Stebbins 2003). Staff recommends that the applicant, USFWS, and CDFG consider the possibility that one or more juvenile tortoises or egg clutches could be found on-site during pre-construction surveys in preparation of the applicable desert tortoise take permits.

Staff's proposed Condition of Certification **BIO-8** recommends a variety of additional impact avoidance and minimization measures to reduce the risk of injury and death to desert tortoise and other special-status species. Staff's proposed Condition of Certification **BIO-9** requires verification that all desert tortoise impact avoidance, minimization, and compensation measures have been implemented.

Desert tortoise clearance surveys and translocation, as described in staff's proposed Conditions of Certification **BIO-14** and **BIO-15** have inherent risks and could themselves result in direct adverse effects to desert tortoises, such as mortality, injury, or harassment of desert tortoises due to equipment operation, fence installation, removal of tortoise burrows, and tortoise translocation. These potential impacts are described in more detail below.

Impacts to Critical Habitat

No direct impacts to designated desert tortoise critical habitat would result from the project. The RSEP solar generator site, generator tie-line alignment, and interconnector substation, are outside the federally designated critical habitat for desert tortoise (USFWS 1994). Western's existing 161-kV Parker-Blythe #2 transmission line alignment is within about one mile of the southeast corner of the Chemehuevi critical habitat unit, near Vidal.

Translocation⁵

All tortoises, including adults, subadults, and juveniles found during clearance surveys on the solar generator site and contiguous disturbance area would be translocated off the site to new locations. However, it is likely that some tortoises, particularly juveniles, and tortoise eggs would be overlooked during clearance surveys because of the cryptic nature of tortoises, especially the juveniles and hatchlings and location of egg clutches

⁵ In this SA/DEIS, translocation is defined as any project-related action involving moving any desert tortoise or tortoise egg from one location to another, regardless of distance. When finalized, the Desert Tortoise Translocation Plan (per Condition of Certification **BIO-14**) shall adhere to resource agency requirements and may or may not distinguish between translocation and relocation, depending upon distance or other factors.

below ground. These tortoises and eggs would be subject to mortality from project activities within the tortoise exclusion fence during construction and future operation of the project. Mortality would be minimized through staff's proposed Conditions of Certification **BIO-8** (Impact Avoidance and Minimization Measures), **BIO-14** (Desert Tortoise Clearance Surveys and Exclusion Fencing), and **BIO-15** (Desert Tortoise Translocation Plan). Any tortoises found on the generator tie-line alignment, interconnector substation site, or the existing 161-kV Parker-Blythe transmission line alignment would be moved from harm's way as needed. Impacts to desert tortoises in these areas would be avoided through staff's recommended Conditions of Certification **BIO-8** and **BIO-14** (above).

Staff estimates that two adult or subadult tortoises would be translocated from the solar generator site and that approximately two juvenile tortoises and ten eggs would suffer mortality during project construction. It is possible that juvenile desert tortoises will be found within the exclusion fence during project construction or operation. Staff does not anticipate that desert tortoises would be translocated during construction or upgrade work for the project's transmission line components. Desert tortoises encountered during construction work on transmission lines would be allowed to leave the construction area or moved short distances as described in staff's recommended Condition of Certification **BIO-8**.

Because handling and translocation causes risk to tortoise survival, all translocated tortoises must be radio-tagged and monitored to evaluate translocation success. If five or more tortoises are translocated, the USFWS (2010a) also requires radio-tagging and follow up monitoring of an equal number of host population tortoises at each translocation site. In addition, USFWS requires radio-tagging and follow-up monitoring of an equal number of tortoises at a selected control site, where no translocated animals have been introduced.

Desert tortoise translocation would require a series of actions including but not limited to the following activities:

1. Identification of the proposed translocation and control sites;
2. evaluation of the habitat quality on the translocation and control sites;
3. determination of existing tortoise density at the translocation site and an assessment of the site's ability to accommodate additional tortoises above baseline conditions;
4. pre-construction fencing and clearance surveys of the project site;
5. construction of holding pens for quarantined translocated tortoises prior to their release into host populations;
6. pre-construction surveys of the proposed translocation sites;
7. placement of tracking units (e.g., GPS transmitters) on tortoises from the project site and, if five or more animals are translocated, at the translocation site and control site;

8. disease testing for tortoises translocated more than 500 m and at the host and control sites;
9. long term monitoring and reporting of control and translocated and host populations; and
10. implementation of remedial actions should excessive predation or mortality be observed.

Capturing, handling, and translocating desert tortoises from the RSEP site after the installation of exclusion fencing could result in harassment and possibly injury or death. Impacts of translocation upon desert tortoises may include elevated stress hormone levels, changes in behavior and social structure dynamics, increased movement (caused by courting or aversive behavior with other tortoises, avoidance of predators or anthropogenic influence, homing, or seeking out of preferred or familiar habitat), spread of disease, increased competition for resources, and increased predation. Furthermore, handling, holding, and transport protocols may compound with abiotic factors to affect the outcome for translocated individuals (Bertolero et al. 2007; Field et al. 2007; Rittenhouse et al. 2007; Teixeira et al. 2007), particularly during extreme temperatures, or if they void their bladders. Averill-Murray (2001) determined that tortoises that voided their bladders during handling had significantly lower overall survival rates (0.81-0.88) than those that did not void (0.96). If multiple desert tortoises are handled by biologists without the use of appropriate protective measures, pathogens may be spread among the tortoises, both resident and translocated animals. For tortoises near but not within the RSEP site, fencing off habitat within their home ranges would likely result in displacement stress that could result in decrease in health, exposure, increased risk of predation, increased intraspecific competition, or death. Tortoises moved outside their home ranges may attempt to return to the area from which they were moved, therefore making it difficult to isolate them from the potential adverse effects associated with project construction. Mortality for translocated desert tortoise has been estimated at approximately 15% (Sullivan 2008), though recent evidence from the desert tortoise translocation effort conducted in support of the Fort Irwin Land Expansion Project indicates that mortality rates may be closer to 25% per year (Gowan and Berry 2010).

Success rates of herpetofauna translocations range from 14% to 42%, suggesting that improved methods are needed for future recovery of many reptiles and amphibians (Dodd and Seigel 1991; Germano and Bishop 2009). A recent review of 91 herpetofauna translocation projects reported the primary causes of translocation failure were homing response by translocated individuals and poor habitat in translocation areas, followed by human collection, predation, food and nutrient limitation, and disease (Germano and Bishop 2009). The risks and uncertainties of translocation to desert tortoise are well recognized in the desert tortoise scientific community. The Desert Tortoise Recovery Office (DTRO) Science Advisory Committee (SAC) has made the following observation regarding desert tortoise translocations (DTRO 2009, p. 2):

... consensus (if not unanimity) exists among the SAC and other meeting participants that translocation is fraught with long-term uncertainties, notwithstanding recent research showing short-term successes, and should not be considered lightly as a management option. When considered, translocation

should be part of a strategic population augmentation program, targeted toward depleted Populations in areas containing “good” habitat. The SAC recognizes that quantitative measures of habitat quality relative to desert tortoise demographics or population status currently do not exist, and a specific measure of “depleted” (e.g., ratio of dead to live tortoises in surveys of the potential translocation area) was not identified. Augmentations may also be useful to increase less depleted populations if the goal is to obtain a better demographic structure for long-term population persistence. Therefore, any translocations should be accompanied by specific monitoring or research to study the effectiveness or success of the translocation relative to changes in land use, management, or environmental condition.

To provide guidance for the applicant in addressing these concerns and developing an adequate relocation/translocation plan, the USFWS (2010a) provides guidelines for clearance and translocation of desert tortoises from project sites. This document describes timing of translocations; disease testing and monitoring requirements for tortoises that are translocated and those already at recipient sites; and control site monitoring for translocation projects involving more than 5 desert tortoises. USFWS standards require disease testing and quarantine for any tortoise translocated more than 500 meters (985 feet). This requirement is intended to limit the potential exposure risk to healthy tortoises in adjacent habitat.

The applicant submitted a Draft Desert Tortoise Relocation/Translocation Plan for the RSEP as Appendix A of the Draft Biological Assessment (CH2MHill 2010c). Based on the results of 2009 protocol surveys, the applicant estimates that fewer than five desert tortoises would require translocation from the project site (Appendix A of CH2MHill 2010c). The Draft Desert Tortoise Relocation/Translocation Plan proposes private, applicant-owned land adjacent to the solar field site as a translocation area. The proposed translocation site is proposed for long-term conservation under a conservation easement (Appendix A of CH2MHill 2010c). These adjacent lands provide similar habitat and staff has concluded, in consultation with CDFG, USFWS, BLM, and Western biologists, that they would be suitable as a translocation site and as compensation land as described in staff’s proposed Condition of Certification **BIO-16** (below).

Staff’s proposed Condition of Certification **BIO-15** requires the applicant to prepare and implement a Desert Tortoise Translocation Plan in consultation with staff, BLM, CDFG, and USFWS, to be based on the draft Plan described above and to conform to USFWS guidelines (2010a). The final plan will provide additional details, including applicable monitoring and disease testing requirements for translocated tortoise(s).

Mitigation for Desert Tortoise Habitat Loss

Construction of the proposed RSEP facility and associated facilities would result in the permanent and long-term loss of approximately 1,770 acres of occupied desert tortoise habitat, (see **Biological Resources Table 3**; for the purpose of estimating project impacts, staff includes all impacts except the 6-acre concrete pad and uses the higher acreage for each project component where an acreage range is indicated). The quality of the habitat on the solar field site is lower than that along the generator tie-line and interconnection substation, as the solar field site was historically disturbed by the Rice

Army Airfield. Staff noted on site visits in April, 2010 that soils on much of the site appeared somewhat compacted, and the density and diversity of native vegetation is lower than that on undisturbed areas adjacent to the site. Nonetheless, a live desert tortoise, desert tortoise remains, egg shell fragments, burrows, and tracks were all observed on the site during the 2009 protocol surveys. Sign and live tortoises were also observed along the generator tie-line route and in areas adjacent to the route and the solar field site (see **Biological Resources Table 7** above). Staff believes that similar habitat and tortoise occurrence should be expected on the existing 161-kV Parker-Blythe #2 transmission line alignment.

Habitat along the generator tie-line route appears to be of higher quality for desert tortoises than that found on the solar field site. Soils are more friable, there is no evidence of historic compaction, paving, or oiling; native vegetation is denser and more diverse; wildlife sign (burrows, scat, etc.) is more common; and a large, broad wash supporting microphyll woodland occurs along the route. Further, impacts along the proposed new tie-line alignment would be immediately adjacent to a BLM wilderness area. These impacts include a new access road, with associated edge effects such as weed propagation, introduced into otherwise inaccessible and undisturbed natural habitat.

The solar generator facility and interconnector substation would be surrounded by perimeter fencing designed to exclude tortoises and other wildlife. The generator tie-line and existing 161-kV Parker-Blythe #2 transmission line alignments would not be fenced, but habitat would be lost permanently or long-term through the construction of a 5.4-mile new access road, transmission tower construction sites, other construction disturbance (road improvements, structure access areas, pull sites, lay-down areas, etc.). The fenced solar field site would also disrupt tortoise and other wildlife movement and contribute to reduced tortoise movement opportunity among habitat areas. Compensatory mitigation is required to offset this significant impact and to fully mitigate adverse project impacts to desert tortoise. Compensatory mitigation for desert tortoise typically involves balancing the acreage of habitat loss with acquisition of lands that would be permanently protected and enhanced to support viable tortoise populations. The compensation comes about by improving habitat conditions of the acquired property so that more desert tortoises are likely to survive and reproduce on these lands, thus offsetting over time the decrease in numbers of tortoise resulting from the habitat loss.

For the acquisition of mitigation lands to truly compensate for the habitat loss and to make up for the numbers of desert tortoise that would otherwise have been supported by that habitat, the acquisition must be accompanied by (1) permanent protection and management of the lands for desert tortoise, and (2) enhancement actions. The permanent protection is essential because that allows the lands to be managed in a way that excludes multiple threats and incompatible uses (e.g., grazing, off-highway vehicle use, roads and trails, utility corridors, military operations, construction, mining, grazing by livestock and feral burros, invasive species, fire, and environmental contaminants). Without this protection and management the desert tortoise populations on the acquired lands would be subject to the same threats that led to its population declines and threatened status. An equally important component is the implementation of enhancement actions to improve desert tortoise survival and reproduction. These

actions could include habitat restoration, invasive plant control, road closures or road fencing, reducing livestock and burro grazing, and controlling ravens and other predators.

To mitigate the loss of desert tortoise habitat under CESA, CDFG usually requires a mitigation ratio for compensation lands of 1:1 for low-quality suitable habitat and a ratio greater than 1:1 for impacts to better quality habitat (i.e., acquisition of more than one acre of compensation lands for each acre lost). CDFG typically uses a 3:1 ratio or higher for good quality habitat such as that found along the generator tie-line alignment. This higher ratio for the impacts along the generator tie-line and related disturbance is based on (1) absence of soil compaction, pavement, or oiling found at the former airfield site; (2) the geographic nature of the disturbance, which would create multiple new, localized disturbed sites which can become sources of weed infestations or other disturbances into surrounding undisturbed desert lands; (3) the 5.4 miles of new roadway, which could lead to increased noise and other human disturbances as recreational motorists make use of the new access route; and (4) the generator tie-line alignment's location at the boundary of a BLM Wilderness Area, which has higher conservation priority than most other desert lands.

The applicant has proposed to provide compensation lands at a 1:1 ratio to mitigate for permanent impacts to desert tortoise habitat (SR 2009a; CH2MHill 2010c). Staff and CDFG propose that a mixed habitat compensation ratio should be implemented for the RSEP. The rationale for the mixed ratio is that tortoise habitat quality and long-term habitat value for tortoise varies between the solar field site and the transmission corridor/substation site, primarily due to historic disturbance on the solar field site. In consultation with USFWS, BLM, and CDFG biologists, staff has concluded that a mitigation ratio of 1:1 (i.e., acquisition and preservation of one acre of compensation lands for each acre of project disturbance) would reduce permanent and long-term impacts to approximately 1,661 acres of lower quality habitat at the solar generator site to less than significant. In the absence of further information about habitat quality along the existing 161-kV Parker-Blythe #2 transmission line alignment, staff includes the estimated 127 acres of disturbance for OHGW installation within the habitat impacts to be mitigated at 1:1. For permanent and long-term impacts to approximately 109 acres of higher-quality habitat along the generator tie-line, access road, and at the interconnector substation, a mitigation ratio of 3:1 would reduce impacts to less than significant.

Habitat compensation would consist of land dedication and protection for all project impacts to desert tortoise habitat on private lands. For impacts on public (BLM) lands, compensation may consist of land dedication and protection at a 2:1 mitigation ratio and an additional assessed financial contribution at a 1:1 ratio, so that total compensation is at a 3:1 ratio for impacts to BLM lands, as described in the following sections. This mitigation strategy is consistent with measures in Incidental Take Permits issued by CDFG for projects in the region, and with requirements described in the NECO (BLM and CDFG 2002).

Biological Resources Table 8.
Summary of Impact Estimates and Compensation Ratios for Desert Tortoise Habitat¹

Project component	Disturbance acreage	Compensation Ratio	Compensation acreage
Solar generator site, including permanent and long-term disturbance within and outside perimeter fence; all applicant-owned land; and 127 acres estimated disturbance on Parker-Blythe #2 transmission line.	1,661 acres	1:1	1,661 acres
Total permanent and long-term disturbance for generator tie-line, access road, and interconnector substation (includes approx. 20 acres private land and 97-99 acres BLM land).	109 acres	3:1	327 acres ²
Acreage Totals	1,770 acres		1,988 acres

1. For the purpose of estimating project impacts, staff includes all impacts except the 6-acre concrete pad and uses the higher acreage for each project component where an acreage range is indicated. See **Biological Resources Tables 2 and 3**.
2. Compensation for impacts to BLM land may consist of 2:1 habitat compensation and 1:1 habitat enhancement (financial contribution to be based on estimated cost of acquisition).

State and Federal Desert Tortoise Habitat Compensation Requirements

To satisfy the full mitigation standard under CESA (California Fish and Game Code Section 2081) and to comply with requirements of a State Incidental Take Permit for desert tortoise, the proposed mitigation must meet criteria described in Title 14 CCR, Sections 783.4(a) and (b). These criteria include requirements that the proposed mitigation would be capable of successful implementation and that adequate funding is provided to implement the required mitigation measures and to monitor compliance effectiveness of the measures. In order to ensure that the project meets these requirements, CDFG typically requires and the Energy Commission would require that lands acquired as mitigation for a listed species must be managed and protected in perpetuity for the benefit of that species. The mitigation ratios described above are consistent with habitat compensation ratios as required by CDFG and the Energy Commission for impacts to desert tortoise and other listed threatened or endangered species, based on habitat quality.

The approach to desert tortoise mitigation for the RSEP must also satisfy BLM's policies for lands within the NECO planning area (BLM and CDFG 2002). The NECO specifies the following desert tortoise compensation requirements (from page D-2, Appendix D, BLM and CDFG 2002):

A mitigation fee based on the amount of acreage disturbed shall be required of proponents of new development. Within Desert Wildlife Management Areas (DWMAs) (Category I) the lands delivered or equivalent fee shall be an amount that achieves a ratio of 5 acres of compensation land for every 1 acre disturbed. Outside DWMAs (Category III) the lands delivered or equivalent fee shall be an amount that achieves a ratio of one (1) acre of compensation land for every 1 acre disturbed. Funds may be expended as approved by the Management

Oversight Group in 1991. Lands will be acquired or enhanced within the same recovery unit as the disturbance. CDFG may require additional fees for management of lands and for rehabilitation of lands.

Consistent with NECO direction, staff recommends that for permanent and long-term impacts to desert tortoise habitat on BLM-managed lands, the BLM portion of the mitigation ratio shall be 1:1 outside of designated critical habitat or Desert Wildlife Management Areas. The proposed project does not cross any DWMA's or other special management areas, and all BLM lands impacted by the RSEP are classified as Category III lands.

As specified in staff's proposed Condition of Certification **BIO-16**, acquisition, protection and enhancement of desert tortoise habitat, in combination with the requirements of **BIO-14**, **BIO-15** and **BIO-17**, would mitigate project impacts to desert tortoise. Acquisition of appropriate mitigation lands as described in **BIO-16** would secure and protect desert tortoise habitat.

Staff's proposed Condition of Certification **BIO-16**, Desert Tortoise Compensatory Mitigation, specifies security for acquisition, dedication, and protection of 1,988 acres and provides a estimates of each associated cost. Also, see **Biological Resources Table x**). The estimated composite mitigation cost to meet staff's recommendation for establishing the security would be approximately \$2,622 per acre of compensation land. This security amount may change with updated appraisals and when a Property Analysis Record or similar analysis is prepared for the parcels selected for acquisition. It is important to note that these are estimates based on current cost estimates; the requirement is defined in terms of compensation habitat acreage, not cost, and actual costs may vary.

Integrating State and BLM Desert Tortoise Habitat Compensation

Staff from the Energy Commission, Western, BLM, USFWS, and CDFG agree that compensatory mitigation at the 3:1 and 1:1 ratios described above is appropriate for the RSEP's impacts to desert tortoise habitat. However, some differences remain between the federal and state approach to desert tortoise mitigation that currently preclude a complete integration of desert tortoise mitigation requirements. One difference is the state requirement for permanent protection of acquired mitigation lands. Energy Commission staff and CDFG require that mitigation lands acquired for endangered species be maintained and protected in perpetuity for the benefit of those species. The BLM generally cannot make the same commitment to protecting acquired mitigation lands because the multiple use mandate on most lands it manages restricts its ability to designate lands solely for conservation purposes or to exclude potentially incompatible development and activities.

The Renewable Energy Action Team (REAT) Agencies (Energy Commission, BLM, CDFG, and USFWS) agree that to address the in-perpetuity protection requirement, any lands acquired and subsequently donated to BLM will have either a deed restriction or conservation easement in title that will preclude future development of the land. The REAT Agencies also note that protection could be achieved by buying private in-holdings within designated wilderness or wilderness study areas, being that these areas

are congressionally designated and as such preclude incompatible land uses within their boundaries, thus meeting the requirement for in perpetuity protection. The BLM has an established process for accepting lands with deed restrictions or conservation easements and is working on streamlined version of this process. Staff anticipates that the streamlined process for in-perpetuity protection of BLM mitigation lands will be established before the end of 2010 (Fesnock pers. comm., Flint pers. comm.).

Rather than just purchasing compensation lands, BLM may use a portion of the compensation funds to implement desert tortoise habitat enhancement measures. These measures may include, but would not be limited to: habitat restoration and invasive plant control, eliminating livestock and burro grazing, fencing to exclude livestock and vehicles or reduce the incidence of road strikes, controlling tortoise predators such as ravens, feral dogs and coyotes, as well as increased law enforcement, signage and education.

The BLM has also indicated that for any land enhancement actions or recovery actions implemented on existing BLM-owned lands, BLM would develop a Memorandum of Understanding (MOU) with CDFG containing provisions for notification of any proposed Projects affecting those lands (BLM 2009a). The BLM agreed that future Projects authorized on these mitigation lands would be compensated at a higher rate (BLM 2009a).

Staff believes that habitat enhancement measures, in combination with habitat acquisition, would feasibly and effectively mitigate the project's impacts to desert tortoises. The measures outlined above are consistent with the USFWS desert tortoise recovery plan recommendations (USFWS 1994, 2008a), which describe actions in addition to land acquisition that could reduce threats to desert tortoise populations. Staff agrees that fencing, retirement of grazing allotments, removal of burros, and habitat restoration show considerable promise as actions that could increase desert tortoise survivorship and reproduction in portions of its range. These measures would address specific known threats to desert tortoise as identified in the Recovery Plan (USFWS 1994b), Draft Revised Recovery Plan (2008a) and Spotlight Species Action Plan (USFWS 2009e). These threats, which may be relieved in part through the habitat enhancement measures listed above, include proliferation of roads; off-highway vehicle activity; deliberate maiming, killing, or collecting; habitat invasion by non-native invasive species; and increased frequency of wildfire due to invasion of desert habitats by non-native plant species.

The amount of the security deposit (calculated below) is based upon estimated cost to purchase and protect mitigation land at the ratios described above. BLM may use no more than the portion of the fund that corresponds to a 1:1 ratio for staff's estimated purchase and protection cost for long-term and permanent impacts to desert tortoise habitat on BLM lands (99 acres as shown in Biological Resources Table 2 and additional land disturbed on the existing 161-kV Parker-Blythe transmission line) to implement habitat enhancement measures as described above. The remainder of the mitigation obligation shall be used only for compensation land acquisition and protection, initial improvement and management.

Calculation of Security for Desert Tortoise Habitat Compensation

Staff's proposed Condition of Certification **BIO-16** specifies compensatory mitigation for desert tortoise habitat loss at a 1:1 ratio for the solar field site and for habitat loss along the existing 161-kV Parker-Blythe #2 transmission line alignment and at a 3:1 ratio along the generator tie-line alignment and at the interconnection substation site.

To satisfy Section 2081 of the California Endangered Species Act, the applicant must provide financial assurances to guarantee that an adequate level of funding is available to implement all impact avoidance, minimization, and compensation measures described in the desert tortoise conditions of certification. These financial assurances are generally provided in the form of an irrevocable letter of credit, a pledged savings account or another form of security prior to initiating ground-disturbing project activities. Staff's proposed conditions of certification typically specify the dollar amount of the security, and include a provision for adjusting that security amount when parcel-specific information is available. This security amount is calculated by multiplying the required compensation mitigation acreage by the estimated total per acre costs, a figure which represents the sum of the costs required for: (1) land acquisition, (2) initial habitat improvements, and (3) a long-term maintenance and management fee to support long-term management of the acquired lands.

The latter cost for the long-term management endowment is typically the largest component of the mitigation fee. Interest or earnings from the endowment creates a long term funding source to provide enough income to cover annual stewardship costs on the acquired lands and includes a buffer to offset inflation. The amount for the endowment is established by a Property Analysis Record (PAR) or PAR-like analysis. PAR is a database method developed by the Center for Natural Lands Management (<www.cnlm.org/cms>) which calculates the costs of in perpetuity land management activities for a particular parcel. These activities include development of a desert tortoise management plan tailored for each parcel of mitigation land to assess habitat status, identify desired conditions, and develop plans to achieve conditions that would best support desert tortoise. Once the management plan is developed and approved by the appropriate resource agencies, implementation of enhancement actions such as fencing, road closure, weed control, habitat restoration as well as monitoring can begin. The goal of these activities is to increase the carrying capacity of the acquired lands for desert tortoise and increase their population numbers by enhancing survivorship and reproduction.

Funding for the initial habitat improvements supports those actions needed immediately upon acquisition of the property to secure it and remove hazards. These activities might include fencing or debris clean-up, or other urgent remedial action identified prior to when the parcels were acquired. When the management plan is completed for the acquired parcel activities like these are thereafter funded from the interest produced by the long-term management maintenance fee described above.

In contrast to the state mitigation approach, the BLM does not require a long-term maintenance and management fee or other funding to manage the acquired desert tortoise mitigation lands because they pursue recovery goals through implementation of region-wide management plans and land use planning as described in the NECO and

the Desert Tortoise Recovery Plan rather than through parcel by parcel acquisitions and management. The BLM typically requires a cash payment (proffer) prior to initiating ground-disturbing activities, which generally includes a per acre cost reflecting current land value and recent purchase prices, as well as additional acquisition and indirect costs and funding for appraisals, environmental site assessments, property cleanup, and an inflation contingency. However, as noted by the REAT agencies, other methods may be employed which would satisfy both BLM and the state agency legal requirements.

The applicant may elect to purchase and permanently protect compensation lands itself; to fund the acquisition and initial improvement of compensation lands through NFWF by depositing funds for that purpose into NFWF's REAT Account as outlined in **BIO-16**. Further, **BIO-16** would require that the project owner provide financial assurances to guarantee an adequate level of funding to implement the compensation measures described above. Because there are several suitable options available to the applicant to satisfy the compensation requirement, and because mitigation requirements must satisfy the requirements of both state and federal Endangered Species Acts, staff's calculation of the security amount includes estimates of all transaction and management fees described above. These calculations are presented in **Biological Resources Table 10** in the Conclusion section, below.

Location of Acquired Habitat Compensation Lands

The RSEP solar field site is located within a 3,324-acre holding owned by the applicant. The applicant proposes to apply lands within the holding, but outside the RSEP footprint area, as desert tortoise compensation lands. Energy Commission staff, in coordination with BLM, CDFG, Western, and USFWS biologists, tentatively agree that these lands are largely suitable as compensation for project impacts to desert tortoise habitat, with some exceptions. Staff concludes that habitat values within a 250-foot buffer area surrounding the project footprint would be reduced due to indirect and off-site project impacts such as noise, lighting, ground vibration, human disturbance, weed introductions, and other effects (see **Construction Impacts to Vegetation and Construction Impacts to Common Wildlife and Habitat**, above; and **Operations Impacts to Birds and Common Wildlife**, below). Therefore, staff recommends this 250-foot buffer area surrounding the perimeter fence (estimated as 165 acres), if included as desert tortoise compensation land, should be credited at the reduced mitigation value of 0.5:1 rather than 1:1. That is, the approximately 165-acre area would be credited as only 82.5 acres of mitigation land. For similar reasons, staff recommends that applicant-owned lands between SR-62 and the project footprint (i.e., north of the heliostat perimeter and administrative area, estimated as 230 acres) also should be credited at the reduced mitigation value of 0.5:1 rather than 1:1. This area would be credited as only 115 acres of mitigation land. Based on these approximations, staff estimates that applicant-owned land contiguous to the project area could account for approximately 1,486 acres of the required 1,998 acres of desert tortoise compensation habitat as recommended in Condition of Certification **BIO-16**.

Staff's estimated compensation and security cost described above, and in Condition of Certification **BIO-16** and **Biological Resources Table 10**, assumes that the applicant would purchase all compensation land or provide cash funding to a REAT NFWF

subaccount as described in **BIO-16** and **Biological Resources Table 6**. Staff recognizes that much of the compensation mitigation would likely be acreage currently owned by Solar Reserve, but some uncertainties remain. In consultation with CDFG, staff recommends that the applicant transfer fee title to the Lands to CDFG under terms approved by CDFG. Alternatively, a CDFG-approved non-profit organization qualified pursuant to California Government Code section 65965 may hold the fee title or a conservation easement over the Lands. In the event an approved non-profit holds title, a conservation easement shall be recorded in favor of DFG in a form approved by CDFG; in the event an approved non-profit holds a conservation easement over the Lands, CDFG shall be named third party beneficiary. Staff further recommends requiring the security as described in Condition of Certification **BIO-16** and **Biological Resources Table 10**, pending confirmation that applicant-owned compensation lands meet the selection criteria described in BIO-16, and until establishment of a conservation easement or title transfer, PAR or PAR-like analysis, long-term management and maintenance fund, and all other associated costs and activities for the compensation land are complete. Staff anticipates that much or all of the project's compensation requirement could be satisfied relatively quickly through dedication of applicant-owned lands.

Except as noted above, areas within the holding but outside of the permanent project fencing are contiguous to the solar field site and provide similar habitat values. These adjacent lands that are already owned by the applicant and may be used to fulfill part or all of the State mitigation requirements of proposed Condition of Certification **BIO-16**. If the applicant chooses not to use these lands for mitigation, then staff recommends that alternate lands should be identified and acquired offsite, but should be located within the same recovery unit as the proposed project (Colorado Desert Recovery Unit, as identified in the *Draft Revised Recovery Plan for the Mojave Population of the Desert Tortoise (Gopherus agassizii)* (USFWS 2008a).

Indirect Effects to Desert Tortoise

Construction-related indirect effects to desert tortoises would be similar to those described for common wildlife, above. Additional indirect effects to desert tortoises would occur during operations of the RSEP. These include loss of forage, burrowing sites, and cover sites, the spread of non-native invasive plants, loss of dispersal areas and connectivity to other areas, reduced home ranges, and increased risk of predation by predators (primarily ravens) attracted to the area by increased human activity. Staff's recommended Condition of Certification **BIO-17** would require raven management on-site and payment on a per-acre basis into a region-wide raven management plan. Each of these impacts is discussed in more detail below, under the discussion of operational impacts.

Conclusion: Summary of Desert Tortoise Impacts and Mitigation

The project would result in permanent or long-term habitat loss and degradation totaling approximately 1,770 acres. Staff also concludes that project implementation would necessitate translocation of two adult or subadult tortoises, and mortality of approximately two juvenile tortoises and ten eggs. Because fewer than five tortoises are expected to be translocated, there would be no requirement for handling additional tortoises at translocation sites or control sites.

Staff has developed proposed conditions of certification to reduce significant impacts to desert tortoise to less than significant under CEQA and to fully mitigate these impacts under CESA. These include staff's proposed Conditions of Certification **BIO-1** through **BIO-9**, which apply to protection of desert tortoise and other biological resources in and near the RSEP. Staff's proposed Conditions of Certification **BIO-14** through **BIO-17** would require additional measures, including installation of tortoise exclusion fencing; clearance surveys; translocation; monitoring; habitat compensation through the acquisition, protection, management, and enhancement of compensation lands; predator management and control; and verification that all measures are implemented.

Staff concludes that implementation of these conditions would reduce impacts at the solar generator site, generator tie-line alignment, and interconnector substation to desert tortoise to less than significant levels under CEQA and would also satisfy the CESA requirements to fully mitigate impacts to desert tortoise under California Fish and Game Code Section 2081. The conditions would minimize habitat disturbance to only that necessary for project development; would prevent desert tortoises from entering the project site through installation of exclusion fencing; would require removal and translocation of tortoises now present on the project site; and would compensate for habitat loss through off-site habitat acquisition. All of these measures would be monitored and verified according to provisions set forth in the conditions of certification. Staff has not determined potential significance of project impacts along Western existing Parker-Blythe #2 Transmission Line.

Impacts to Special-Status Birds: Overview

The desert vegetation and adjacent mountains provide foraging, cover, or breeding habitat for a variety of resident and migratory birds. During field surveys of the site, including the generator tie-line alignment and desert tortoise zone of influence transects, the applicant identified 19 bird species (Appendix 5.2C of SR 2009a; CH2MHill 2010e). Three special-status birds have been documented on or over the site. These are: loggerhead shrike, burrowing owl, and prairie falcon. Prairie falcon and golden eagle nest in the surrounding mountains. There are golden eagle nesting territories in the Turtle, Arica, and West Riverside mountains (Bloom 2010), and prairie falcon territories in the Arica and Little Maria mountains, bordering Rice Valley (CDFG 2010a; Bloom 2010). Both species are likely to utilize the project site for foraging year-around, including during nesting season. Special-status shrubland species, including loggerhead shrike and Le Conte's thrasher, may nest onsite. Burrowing owls evidently winter on-site but probably were not breeding there during 2009 or 2010. Several special-status raptors, including merlin, sharp-shinned hawk, and ferruginous hawk, may utilize the project site during winter for foraging, though no wintering bird field survey data are available. Swainson's hawk (State-listed threatened) could briefly visit the site during spring or fall migration, though it would not be expected to nest or winter in the area.

There are no field survey data or habitat descriptions available for Western's existing 161-kV Parker-Blythe #2 transmission line alignment. Based on a review of Google Earth aerial views of the alignment, the transmission line appears to cross several washes, some of which may support riparian vegetation or desert microphyll woodland vegetation. A variety of special status birds not addressed below could occur in these

habitats. Desert riparian habitat, if present on the alignment, may support breeding habitat for several special status bird species including listed threatened or endangered species (least Bell's vireo or southwestern willow flycatcher). Desert microphyll woodland is a more productive habitat than surrounding uplands and supports breeding desert bird species in higher densities (Laudenslayer 1988). During migration seasons, is important as stopover habitat for large numbers of migratory songbirds.

Golden Eagle

The project site does not provide suitable golden eagle nesting habitat. There are three golden eagle territories within a 10-mile radius of the RSEP site (Bloom 2010) in the Turtle Mountains, West Riverside Mountains, and Arica Mountains, though nest sites in those territories were inactive in May 2010. The entire RSEP project area, including the proposed generator tie-line alignment and existing 161-kV Parker-Blythe transmission line alignment, provides potential foraging habitat, though staff notes that small mammal productivity on the solar generator site appears to be low. Staff expects that golden eagles forage occasionally on the site at any time of year, particularly during winter and migration seasons due to larger numbers of golden eagles in the region and their larger winter foraging ranges.

Proximity of golden eagle nesting territories to the 161-kV Parker-Blythe transmission line is unknown. If the transmission line passes near a nesting territory, then human activity and construction disturbance during installation of the fiber optic OPGW could adversely affect golden eagle nesting success. Human intrusions near golden eagle nest sites have resulted in nest abandonment; high nestling mortality when young go unattended due to altered behavior by the parent birds; premature fledging; and ejection of eggs or young from the nest (reviewed by Pagel 2010). Nest-site abandonment would constitute take under the Bald and Golden Eagle Protection Act.

Construction and operation at the proposed RSEP solar generator, generator tie-line and interconnector substation sites have no potential to affect golden eagle nest sites, but do have the potential to eliminate foraging habitat within range of known nesting territories and by creating flight collision or incineration hazards. These collision and incineration hazards are primarily associated with long-term effects of the solar generator and generator tie-line operations, and are addressed below under **Impacts during Operation**.

During years when golden eagles nest in the territories surrounding the RSEP site, the proposed project could have a significant effect on their foraging habitat. The proposed RSEP would disturb or eliminate a large area of suitable golden eagle foraging habitat. Staff concludes that project impacts to foraging habitat surrounding known golden eagle nesting territories would be significant in terms of CEQA. Due to the larger foraging ranges and greater behavioral flexibility of non-nesting golden eagles (i.e., birds using the area during winter or migration seasons, and unmated birds in the area even during breeding season), staff concludes that adverse impacts to foraging habitat for non-breeding golden eagles would be less than significant.

Implementation of staff's proposed Conditions of Certification **BIO-1** through **BIO-10** would minimize impacts to potential golden eagle foraging habitat. Condition of

Certification **BIO-16** would require compensatory land acquisition to mitigate impacts to desert tortoise (described above); staff believes that protection of these compensatory lands would be likely to protect foraging habitat for golden eagles. Staff concludes that no additional mitigation is required to reduce potential impacts of the solar generator site, generator tie-line alignment, and interconnector substation to golden eagle foraging habitat below a level of significance. Staff has not determined potential significance of project impacts along Western existing Parker-Blythe #2 Transmission Line.

Staff also recommends Condition of Certification **BIO-18** which would require a compilation of existing field survey data for all known or potential golden eagle nesting territories within visual contact or within two miles of Western's existing 161-kV Parker-Blythe transmission line alignment and, for any portions of the alignment where no protocol survey data are available, new nest surveys. Staff's recommended Condition of Certification **BIO-25** would require preparation and implementation of an Avian and Bat Protection Plan, to be reviewed and approved by USFWS, to specify measures to mitigate or prevent adverse project impacts to birds, including impacts to golden eagle nesting territories. Condition of Certification **BIO-18** also would require early season pre-construction surveys for golden eagle nests within a 10-mile radius of the RSEP solar generation site in conformance with methods recommended by Pagel et al. (2010). These surveys would serve to further document golden eagle nesting activity in the area, but would not alter staff's conclusions regarding significance of the project's impacts or recommended mitigation measures. Staff concludes that implementation of these measures would prevent or mitigate potential project impacts of the solar generator site, generator tie-line alignment, and interconnector substation to golden eagle nesting territories to less than significant under CEQA and would prevent take under the Bald and Golden Eagle Protection Act because they would identify golden eagle nest sites and nesting territories and would limit any project-related impacts to those areas only to activities approved by USFWS in its review of the Avian and Bat Protection Plan. Staff concludes that no additional mitigation is required to reduce potential impacts of these project components to golden eagle nesting territories below a level of significance. Staff has not determined potential significance of project impacts along Western existing Parker-Blythe #2 Transmission Line.

Prairie Falcon

A prairie falcon was observed flying over the project site during field surveys reported by the applicant (SR 2009a) and active prairie falcon nests are reported in the area (Bloom 2010). The project's potential impacts to prairie falcon nesting and foraging habitat would be similar to those described above for golden eagle. Proximity of golden eagle nesting territories to the 161-kV Parker-Blythe transmission line is unknown. If the transmission line passes near a nesting territory, then human activity and construction disturbance during installation of the fiber optic OPGW could adversely affect prairie falcon nesting success, as described above for golden eagles. Construction and operation at the proposed RSEP solar generator, generator tie-line and interconnector substation sites have no potential to affect prairie falcon nest sites, but do have the potential to eliminate foraging habitat within range of known nesting territories and by creating flight collision or incineration hazards. These collision and incineration hazards are primarily associated with long-term effects of the solar

generator and generator tie-line operations, and are addressed below under **Impacts during Operation**.

The prairie falcon holds no special protection under the federal Bald and Golden Eagle Act, and is not Fully Protected under the California Fish and Game Code, but it is a bird of prey, and protected under California Fish and Game Code Section 3503.5. The proposed RSEP would disturb or eliminate a large area of suitable prairie falcon foraging habitat within range of known nesting areas. This impact could be significant under CEQA. Due to the larger foraging ranges and greater behavioral flexibility of non-nesting prairie falcons (i.e., birds using the area during winter or migration seasons, and unmated birds in the area even during breeding season), staff concludes that adverse impacts to foraging habitat for non-breeding golden eagles would be less than significant.

Implementation of staff's proposed Conditions of Certification **BIO-1** through **BIO-10** would minimize impacts to prairie falcon foraging habitat. Condition of Certification **BIO-16** would require compensatory land acquisition to mitigate impacts to desert tortoise (described above); staff believes that protection of these compensatory lands would be likely to protect foraging habitat for prairie falcon. Staff concludes that no additional mitigation is required to reduce potential impacts to prairie falcon foraging habitat below a level of significance.

Staff's recommended Condition of Certification **BIO-25** would require preparation and implementation of an Avian and Bat Protection Plan, to be reviewed and approved by USFWS, to specify measures to mitigate or prevent adverse project impacts to birds, including impacts to prairie falcons. Staff concludes that implementation of these measures would prevent or mitigate potential project impacts of the solar generator site, generator tie-line alignment, and interconnector substation to prairie falcons to less than significant under CEQA. Staff concludes that no additional mitigation is required to reduce potential impacts of these project components to prairie falcon nesting territories below a level of significance. Staff has not determined potential significance of project impacts along Western existing Parker-Blythe #2 Transmission Line.

Burrowing Owl

Implementation of the proposed RSEP would impact nine burrow sites that apparently are active during winter, but were not occupied during spring 2009 or 2010 field surveys (CH2MHill 2010e). Burrowing owl nesting season in the low desert begins in March (Patten et al. 2003) and, if they were nesting on-site in 2009 or 2010, would have been detected during field surveys. Based on these survey results, burrowing owls appear to use the site primarily during winter, though the surveys do not exclude the possibility that the owls nest on the site in low numbers during some years. The entire site provides suitable foraging habitat. The applicant estimates that as many as seven single burrowing owls or nesting pairs may occur on the project site (five on the solar generator site and another two on the generator tie-line alignment) (CH2MHill 2010h). Additional suitable or occupied habitat may also be affected along Western's existing 161-kV Parker-Blythe #2 transmission line.

Direct project impacts to burrowing owls would include the crushing of burrows, removal or disturbance of vegetation, increased noise levels, increased human presence, and exposure to fugitive dust. Indirect impacts could include the loss or degradation of habitat due to colonization by invasive weeds and mowing of native vegetation. Operational impacts include increased human presence from maintenance personnel that would flush or otherwise disturb burrowing owls, invasive plant control activities, exposure to high salinity levels at the evaporation basins, and vehicular use of access roads. Impacts that could occur during operations and maintenance are further discussed below under **Impacts during Operation**.

If burrowing owls are present within or adjacent to a construction zone, project disturbance could destroy occupied burrows or cause the owls to abandon burrows. If owls were breeding on or near the site, construction during the breeding season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to nest abandonment. The loss of occupied burrowing owl habitat (habitat known to have been occupied by owls during the nesting season within the past three years) or reductions in the number of burrowing owls, either directly or indirectly through nest abandonment or reproductive suppression, would constitute a significant impact. Burrowing owls and their nests are protected under federal and State laws and regulations, including the Migratory Bird Treaty Act and California Fish and Game Code Section 3503.5.

Staff recommends Condition of Certification **BIO-19** to reduce impacts to burrowing owls. Condition **BIO-19** prescribes that, should it become necessary to destroy an occupied burrow, whether or not breeding is occurring on the site, the applicant would implement a passive relocation plan and construct artificial burrows. Occupied burrows may not be disturbed during the nesting season (February 1 to August 31). In addition, the applicant would provide compensation land consistent with the California Burrowing Owl Consortium guidelines to offset the loss of foraging habitat (CBOC 1993). Staff estimates total burrowing owl compensation habitat would 135 acres, as described in Condition of Certification **BIO-19**. Compensation lands would be on lands surrounding the artificial burrows, likely on lands presently owned by the project owner.

Implementation of staff's proposed Condition of Certification **BIO-16**, the compensatory mitigation plan for desert tortoise, could further mitigate habitat loss by the preservation of similar vegetation and habitat, depending on the location and burrowing owl occupancy on the compensation lands. With implementation of these conditions, staff concludes that potential impacts of the solar generator site, generator tie-line alignment, and interconnector substation to burrowing owls would remain adverse but would be mitigated to less than significant under CEQA because new burrow sites would be provided for displaced burrowing owls and suitable habitat would be dedicated and protected in perpetuity to offset habitat loss on the project site. Staff has not determined potential significance of project impacts along Western existing Parker-Blythe #2 Transmission Line.

Special-Status Wintering/Migratory Raptors

Several migratory raptor species, including Cooper's hawk, sharp-shinned hawk, ferruginous hawk, northern harrier, merlin, and Swainson's hawk spend winters in the southern California deserts or, (for Swainson's hawk) migrate through the region en

route to wintering habitat farther south. The project would eliminate or degrade foraging habitat throughout the proposed solar generator site and, to a lesser extent, on the generator tie-line alignment and at the interconnector substation site. Additional foraging habitat may also be affected along Western's existing 161-kV Parker-Blythe #2 transmission line.

Due to the larger foraging ranges and greater behavioral flexibility of raptors outside the breeding season, staff concludes that adverse impacts to foraging habitat for wintering and migratory raptors would be less than significant. Potential operations impacts of the proposed project, including collision with project facilities, or burning in flight near the central tower or standby points, are addressed below (**Impacts during Operations**).

Special-Status Desert Shrubland Passerine Birds

Several special-status perching birds could occur on the project site, generator tie-line alignment, or near enough to these facilities to be affected by noise and other disturbances. These birds include loggerhead shrike (documented on or near the site), Le Conte's thrasher, Crissal thrasher, and black-tailed gnatcatcher. Additional suitable or occupied habitat may also be affected along Western's existing 161-kV Parker-Blythe #2 transmission line. Potential project impacts to these birds would be as described above (**Construction Impacts to Common Wildlife and Habitat; Construction Impacts to Common Migratory and Resident Birds**) and below (**Impacts during Operation**).

Staff's proposed Conditions of Certification **BIO-1** through **BIO-10**, and **BIO-13** which requires pre-construction nest surveys and impact avoidance measures, would minimize impacts to special-status desert shrubland passerine birds. Implementation of staff's proposed Condition of Certification **BIO-16**, the compensatory mitigation plan for desert tortoise, could further mitigate habitat loss by the preservation of similar vegetation and habitat, depending on the location and passerine bird occupancy on the compensation lands. With implementation of these conditions, staff concludes that potential impacts of the solar generator site, generator tie-line alignment, and interconnector substation to special-status passerine birds would remain adverse but would be mitigated to less than significant under CEQA because direct impacts to active nests would be avoided and impacts to habitat would be minimized and compensated. Staff has not determined potential significance of project impacts along Western existing Parker-Blythe #2 Transmission Line.

Impacts to Special-Status Mammals

Nelson's Bighorn Sheep, Burro Deer, and Yuma Mountain Lion

The RSEP solar generator site provides marginally suitable foraging habitat that Nelson's bighorn sheep and burro deer may use infrequently during winter. Both species require regular access to drinking water, especially during summer, but there is no permanent water source on the site and staff is not aware of any suitable nearby wildlife water source. Thus, the site would likely be unsuitable as habitat during summer. Further, the site provides no shaded rest places or escape cover for either species (i.e., dense, shaded desert wash vegetation for burro deer, or steep, rocky slopes for Nelson's bighorn sheep). The site is covered by creosote bush shrubland

which is relatively low in nutritional value and is available in abundance throughout the region. Similarly, the site provides no water or suitable dense shaded cover for Yuma mountain lion. In addition, due to the poor habitat characteristics for deer and bighorn sheep, the site also provides no suitable prey base for mountain lion.

The generator tie-line alignment and interconnector substation site provide similar forage habitat to that on the solar generator site. Portions of the existing 161-kV Parker-Blythe transmission line alignment passes nearer to several mountain ranges, where foraging is more likely due to proximity to cover and regularly occupied habitat.

An important threat to all three species is the reduced opportunity for movement among isolated desert mountain ranges and (for Yuma mountain lion) the Colorado River corridor, where their primary habitat is found. One potential result of this reduced movement opportunity is the decline or extirpation of local populations in individual mountain ranges, perhaps due to a series of poor rainfall years which may cause reproductive failure. Without immigration from another location, declining local populations may become extinct. The proposed project has the potential to adversely impact wildlife movement for many species, including Nelson's bighorn sheep, burro deer, and/or Yuma mountain lion; particularly potential north-south movement between the Turtle Mountains (to the north) and the series of ranges to the south and southwest (the Big Maria, Little Maria, and Granite Mountains).

The regional metapopulation of the Nelson's bighorn sheep is an important management concern in the Colorado Desert. Several portions of its historic range are now unoccupied. The Little Maria, Big Maria, and Riverside Mountains that surround Rice Valley were once occupied by Nelson's bighorn sheep, and CDFG may eventually plan to repopulate these areas if reestablishment does not occur naturally from source populations in the nearby Granite and Turtle mountains (SR 2009a). The Colorado River Aqueduct, Arizona-California railroad, and SR-62 are major barriers and risks to bighorn sheep that might move from the Turtle Mountains south through Rice Valley. The southwestern portion of the original Rice Valley Grazing Allotment was retired due to its proximity to the Palen Mountain bighorn sheep herd, and it is possible that the bighorn from the west or north could move through the Rice Valley. There is a strong potential that the mountains surrounding Rice Valley will eventually be reoccupied by bighorn sheep (SR 2009a). Potential impacts to wildlife movement are discussed further, below, and a strategy is recommended to minimize and mitigate those impacts.

None of these three species are listed as threatened or endangered species, nor are they considered to be at high risk of extirpation. Nelson's bighorn sheep and Yuma mountain lion are CDFG Species of Special Concern. All three species have high public interest and management priority.

Loss of habitat on the solar field and generator tie-line sites, and expected off-site impacts such as noise, lighting, and disturbance, are not expected to significantly affect Nelson's bighorn sheep, burro deer, or Yuma mountain lion except during potential long-distance dispersal through the broader Rice Valley area, discussed below. Construction on the generator tie-line and existing 161-kV Parker-Blythe #2 transmission line alignments would cause temporary disturbance to habitat and long-term degradation of forage quality along the alignments, but these impacts would not be

significant. Potential project impacts to regional wildlife movement for these and other species, including staff's recommended Condition of Certification **BIO-21**, are discussed below (**Impacts to Wildlife Movement**).

American Badger and Desert Kit Fox

American badgers were not detected on the site during field surveys, but the site could be within a badger's foraging home range, or badgers may occasionally travel across the RSEP site. No badger burrows are known from the site, but badgers in the region could construct a burrow on-site in the future. Desert kit fox was detected in the project area (Appendix 5.2C of SR 2009a), and staff noted at least one burrow likely used by desert kit fox on the site. The desert kit fox is not a special-status species, but is protected under Title 14, California Code of Regulations (Section 460), and potential impacts to individual kit foxes must be avoided. Additional suitable or occupied habitat for both animals may also be affected along Western's existing 161-kV Parker-Blythe #2 transmission line.

Potential direct impacts to American badger and desert kit fox include mechanical crushing of individuals or burrows by vehicles and construction equipment, noise, dust, and loss of habitat. The tortoise exclusion fence is expected to entrap desert kit foxes or even badgers if either species is on the site when the fence is built. Animals trapped within the fence would almost surely die from direct or indirect effects of project construction (e.g., vehicle strike, inability to find sufficient food or thermal cover). Potential indirect and off-site impacts include construction and operational noise and disturbance, impediments to local or regional movement, alteration in prey base, introduction or spread of invasive plants, and risk of mortality by vehicle strikes.

Staff's proposed Condition of Certification **BIO-20** requires that, prior to ground disturbance, a qualified biologist perform a preconstruction survey for badger and kit fox dens in the project area, including areas within 250 feet of all proposed project facilities, utility corridors, and access roads. If occupied dens are present, the applicant will flag and avoid them during ground-disturbing activities and establish a buffer to minimize disturbance, including potential disturbance to denning females with young. Should the applicant need to work in an area near an occupied (but non-natal) den, the applicant will slowly excavate the den in accordance with Condition of Certification **BIO-20** and or allow the animal to escape the project area on its own (e.g., by providing a temporary monitored opening in the tortoise exclusion fence and directing the animal toward the opening with temporary plastic construction fencing). Female kit foxes or badgers with young would not be directed off-site until the young are ready to leave the dens. Implementation of **BIO-20** would avoid take of American badger and desert kit fox. Staff's proposed Condition of Certification **BIO-16**, the compensatory mitigation plan for desert tortoise habitat, would offset the loss of habitat for desert kit fox and American badger by providing protection and enhancement for suitable habitat. Implementation of these conditions of certification would reduce impacts to these species to less than significant levels under CEQA.

Special-Status Bats

Several special-status bats (pallid bat, western mastiff bat, California leaf-nosed bat, pocketed free-tailed bat, big free-tailed bat, and Townsend's big-eared bat) could use

the solar generator site, generator tie-line alignment, or interconnector substation site for foraging, but no suitable roosting habitat is available on-site for any of these species. Project construction could impact special-status bats through the elimination of desert shrubland foraging habitat. The solar generator does not appear to provide specialized habitat or other resources for foraging bats other than those resources widely available throughout the region. Due to the absence of suitable roosting habitat on-site or in the area, and due to the very low acreage of microphyll woodland habitat on the site, staff concludes that potential impacts would be less than significant under CEQA.

Suitable or occupied special status bat habitat may be present along Western's existing 161-kV Parker-Blythe #2 transmission line. Construction of the fiber optic OPGW line along that alignment would not necessitate demolition of rock outcrops or other potential roosting area, though construction would necessitate short-term anthropogenic disturbance to potential roost sites on power poles. Staff's recommended Condition of Certification **BIO-6** (Worker Environmental Awareness Program) would require specific training in recognizing and avoiding unnecessary disturbance to roosting bats for all construction workers on the transmission line. However, staff has not determined potential significance of project impacts along Western existing Parker-Blythe #2 Transmission Line.

Impacts to Wildlife Movement

The extent, distribution, and accessibility of suitable habitat affect the long-term viability of regional wildlife populations. Fragmentation and isolation of natural habitat ultimately results in the loss of native species within those areas (Soulé et al. 1988). Wildlife movement among habitat areas is important to long-term genetic variation and demography. In the short term, it may also be important to individual animals' ability to occupy their home ranges, if their ranges extend across a potential movement barrier. These considerations are especially important for rare, threatened, or endangered species such as the desert tortoise, and wide-ranging species which exist in low population densities such as large mammals. Therefore, this discussion of potential project impacts to wildlife movement focuses on desert tortoise and Nelson's bighorn sheep.

In landscapes where native habitats exist as partially isolated patches surrounded by other land uses, planning for wildlife movement generally focuses on "wildlife corridors" to provide animals with access routes among habitat patches. In largely undeveloped areas, including the Rice Valley, wildlife habitat is available in extensive open space areas throughout the region, but specific linear barriers may impede or prevent movement. In these landscapes, wildlife movement planning focuses on sites where animals can cross linear barriers, but may not emphasize linear corridors among habitat areas.

In Rice Valley, the biologically important functions of large mammal movement are the long-term demographic and genetic effects of occasional animal movement among mountain ranges and other large habitat areas. Desert tortoises and other less-mobile animals may live out their entire lives within a "corridor" area between larger habitat blocks; for these species, movement among mountain ranges may take place over the course of several generations (Beier and Loe 1992). However, larger and more mobile

animals such as Nelson's bighorn sheep may travel across the valley infrequently, as a part of dispersal among subpopulations. It is unlikely that any individual animal would need to move across the valley to access different parts of its regular home range.

BLM management strategies for wildlife and habitat, including management to maintain connectivity among habitat areas, include special management of Areas of Critical Environmental Concern (ACECs), Wilderness Areas, Wilderness Study Areas, and Desert Wildlife Management Areas (DWMAs). BLM lands throughout the surrounding area are designated as the Rice Wildlife Habitat Management Area (WHMA), which is managed for sand dune habitat (for the Mojave fringe-toed lizard) and to provide wildlife connectivity between the Chemehuevi Desert Wildlife Management Area/Turtle Mountains Wilderness to the north and Palen-McCoy and Rice Valley Wildernesses to the south. The project site itself is on private land and not under BLM management, but similar wildlife movement values apply to the site.

There are no significant constructed barriers to east-west wildlife movement through the proposed project area and the Rice Valley, south of SR-62. There are three parallel linear structures that limit wildlife north-south movement opportunities in the Rice Valley near of the proposed RSEP site, as described in the applicant's Response to Data Request 59 (CH2MHill 2010a): the Colorado River Aqueduct, Arizona-California Railroad, and SR- 62. See **Biological Resources Figure 4**. The three structures are parallel to one another, running roughly east-west across the valley in a corridor approximately 0.25 mile wide. Any of the three structures alone would impede wildlife crossing for many species. In combination, their impediment effect is substantial. An animal traveling from the Turtle Mountains into the Rice Valley would encounter the aqueduct first, then the railroad, and last, the highway. The proposed RSEP project would be immediately south of the highway.

The aqueduct presents an impassable barrier to terrestrial wildlife along most of its alignment, except at "siphon" points where desert washes cross over the alignment. At these wash crossings, aqueduct water is carried underground through U-shaped siphons over distances of several hundred feet or more. There are 15 such overcrossings within 5 miles east and west of the proposed RSEP site (CH2MHill 2010a, including Figure DR59-1). Within this area, the largest overcrossing is approximately 1,705 feet wide, and is north of the western margin of the proposed RSEP heliostat field. A similar, but narrower, crossing is present north of the eastern margin of the proposed heliostat field.

Burro deer have been documented crossing similar aqueduct siphons in Arizona. The Central Arizona Project (CAP) is a manmade canal that presents a partial barrier to wildlife movement between the Tucson Mountains and Roskrige Mountains, in Pima County, Arizona. There are a series of wildlife crossings over the canal, ranging from 130 to 550 feet wide, similar in design to the siphons on the Colorado River Aqueduct. Several individual burro deer (also called desert mule deer) crossed the CAP at these locations and some of the deer crossed several times (Tull and Krausman 2001). Staff noted coyote tracks and scat at these channel crossings, indicating that coyotes probably cross the aqueduct at those points.

Downstream from each aqueduct siphon, each wash is crossed by the railroad line, which is built on concrete supports and foundations bridging the washes (CH2MHill 2010a, Figures DR59-3a through 3d). The rail crossings north of the RSEP site are approximately 45 feet wide, with about 6 feet of vertical clearance. East and west of the channel crossing, the railbed is elevated a few feet above the surrounding grade. Any terrestrial wildlife species could cross beneath the railroad bridges, though specific behavioral adaptations affect the likelihood that any given species would do so. Mountain lions or desert tortoises would likely cross beneath the bridges routinely if they occur in the area. Deer and bighorn sheep may avoid them if they appear to present a risk of predation. Most medium- to large-sized mammals also could cross the rail line east or west of the channel crossings by simply walking over the raised railbed and tracks. These animals would be at some risk of mortality by being struck by trains, though rail traffic appears to be relatively light on this line.

Downstream from the rail bridges, SR-62 crosses each wash at grade (i.e., there are no bridges or culverts which could allow safe passage across the highway). Any terrestrial wildlife species could cross the highway. Wary or fast-moving animals such as medium- to large-sized mammals would probably cross safely in most crossing attempts, but some road mortality also would be expected. Slower-moving animals, particularly desert tortoise, would be at high risk of mortality during any road-crossing attempt.

During the construction phase of the proposed RSEP project, a security fence surrounding the proposed logistics and laydown areas would be built along the property boundary immediately south of the SR-62 alignment, over a length of about 3,200 feet. The fence would further limit north or south wildlife travel by reducing access to suitable crossing points. Wildlife moving southward through those crossings would be forced to travel longer distances parallel to the highway before continuing southward, and would therefore be at increased risk of road mortality. This fence would be removed after construction, leaving only the circular perimeter fence. Operation impacts of the permanent perimeter fence are described below (**Impacts During Operation**).

During both construction and operations, the proposed RSEP would probably prevent most wildlife movement from the Rice Valley toward the Turtle Mountains by way of the two crossings described above. Animals travelling northward from the valley would be diverted to the east or west by the perimeter fence around the heliostat field. They might reach either of the two nearby crossings by following a semicircle around the fence, but they would be more likely to continue east or west toward another crossing site. Similar crossings are located at periodic intervals to the east and west. The nearest crossings are located 0.4 mile to the west and 1.5 miles to the east.

During both construction and operations, wildlife travelling east or west, parallel to the highway, and encountering the RSEP perimeter fence would be directed north or south around the arc of the exclusion fence. Individuals directed northwards would become confined within the narrow passage between the three barriers (highway, railroad, and aqueduct) north of the RSEP. This path would present a greater risk of road mortality than presently exists in the area.

Staff believes that numerous species, including large mammals (burro deer, Nelson's bighorn sheep, and Yuma mountain lion) and perhaps desert tortoises, may infrequently

cross the three linear barriers north of the proposed RSEP site. The proposed solar generator facility, including the perimeter and security fences, would further limit potential movement. However, due to presence of numerous similar crossing sites to the east and west, and due to the short-term usage of the security fence, staff concludes that the proposed project's construction impacts to wildlife movement would be less than significant. However, in order to minimize highway mortality, staff recommends Condition of Certification **BIO-21**, Fence Locations: Logistics, Lay-down Area, and Access Road. This condition would require that the logistics and lay-down area be redesigned to provide a 100-foot buffer area between the road shoulder and the temporary security fence, and that the security gate on the main access road be relocated to the main fenceline, to remove the fenced barrier to east-west wildlife movement across the access road. The proposed interconnector substation, generator tie-line, and fiber optic OPGW construction along the existing 161-kV Parker-Blythe transmission line would not have significant effect to wildlife movement.

Impacts to Waters of the State

Numerous ephemeral drainage features occur throughout the solar field site and transmission line corridor, generally trending in a north-south orientation (Attachment DR60-1 of CH2MHill 2010a; **Biological Resources Figures 5A through 5D**). As described above under **Jurisdictional Waters**, the applicant conducted a preliminary Jurisdictional Delineation of the solar field site and transmission line route in February and March of 2010. The drainage features delineated in that report fall within CDFG jurisdiction as Waters of the State. Impacts to these drainage features are described below.

The applicant concluded that there are no wetlands on site and no drainages that would fall under federal jurisdiction pursuant to the federal Clean Water Act. The USACE (2010) concurs that drainage features on the proposed solar generator site and generator tie-line alignment are not within federal jurisdiction as defined in the federal Clean Water Act.

There has been no delineation of state or federal jurisdictional streambed features on Western's existing 161 kV Parker-Blythe #2 transmission line alignment, where the new fiber optic OPGW would be constructed.

A total of approximately 82.8 acres of state-jurisdictional ephemeral channels would be directly or indirectly impacted by construction and operation of the solar generator, generator tie-line, and interconnector substation. Streambed acreage on the existing 161 kV Parker-Blythe #2 transmission line is unknown. Staff concludes that all direct or indirect impacts to these channels are subject to California Fish and Game Code Section 1600 regulation. Stormwater flows originating upstream from the project area would be diverted around the perimeter of the site; minor channels throughout the site would be disturbed during construction and plant operations (e.g., by vegetation removal, location of project facilities, vehicle access crossings, etc.). Although some drainages may be avoided during placement of the transmission towers along the generator tie-line, final engineering has not been completed, and drainages are numerous along the alignment. Therefore, design constraints may require some transmission towers to be sited within ephemeral drainages. In addition, the proposed

new access road that would extend for approximately 5.4 miles along the transmission line would cross numerous drainages. Therefore, quantification of impacts to drainages along the transmission line is not possible at this time, but staff includes streambed acreage along the generator tie-line alignment in the total streambed acreage, above.

Direct impacts to drainages would include the removal of native vegetation, including some areas characterized by microphyll woodland; the discharge of fill; and the attenuation of peak flood flows which affect sediment transport. Most of these impacts would occur during access road construction; solar generation site clearing, grubbing, and improvements; and the development of the project's storm water management system. The attenuation of peak storm flows can adversely affect biological resources dependent on these features. Flooding and regular scour is a form of disturbance to which many plant and animal species appear well adapted and is often required to provide suitable nesting or breeding habitat (Busch and Smith 1995). The imposition of artificial stream flows by the attenuation of storm events may affect seedling recruitment at appropriate stream bank elevations, exaggerate drought stress, and increase mortality of seedlings (Mahoney and Rood 1998). In arid systems, this may be particularly important to ensure seedling survival. In addition, the attenuation of flood events may prevent the essential geomorphic disturbance required to create new nursery sites for seedling recruitment while maintaining other areas relatively clear of vegetation within the scour zone that provides habitat for a number of other plant and animal species (Johnson et al. 1976). Non-natural flow regimes may also change the sediment load carried during regular storm events.

Indirect impacts could include alterations to the existing topographical and hydrological conditions and the introduction of non-native, invasive plant species. Construction of the project would result in alterations to the existing hydrology and expected sediment transport across the site. Adverse effects on habitat are created as sediment-starved water removes fine particulate material from the stream course resulting in stream narrowing, erosion of the streambed and banks, and development of a coarse, boulder-dominated streambed (Mount 1995). Conversely, uninhibited storm flows carry a natural mixture of boulder, cobble, gravel, sand, and silt materials that are deposited at different intervals within the floodplain reflective of the strength of the most recent flood event. The diversity and episodic nature of streams and streambed materials creates habitat niches within the floodplain for varying wildlife.

Drainages along the transmission line corridor would not be permanently obstructed by the placement of transmission towers, and crossings such as culvert or Arizona crossings would be installed at locations where the transmission line access road crosses drainages so as not to impede normal flows. Hydrologically, the solar field site would be entirely cut off from surrounding areas, and flow would be diverted around the site by the raised access road. However, the area is relatively flat, with flows primarily moving in a southern direction via a broad, diffuse network of shallow ephemeral drainages. The site is located on a bajada south of the Turtle Mountains, but hydrology across the bajada has been altered by the construction of the Colorado River Aqueduct, Arizona-California Railroad, and SR-62 north of the project site (Attachment DR60-1 of CH2MHill 2010a). In addition, diversion dams were constructed to the north of these features to protect them from flows originating in the Turtle Mountains. These diversion dams direct flows into two major washes which flow through culverts under SR-62 and

onto the project site. Berms were constructed in the northern portion of the project site to divert water around the former Rice Army Airfield. These berms have since been breached, but flows through these berms quickly fan out creating a dispersed flow pattern characteristic of alluvial fans and bajadas (Attachment DR60-1 of CH2MHill 2010a).

Based on the attenuation of storm flows and other project impacts to ephemeral washes, staff and CDFG consider that all of the ephemeral washes on the solar generator site and portions of the washes downstream of the project boundaries would be adversely affected by the proposed project.

Staff considers permanent and long-term impacts of the project to State jurisdictional waters to be significant. The ephemeral drainages in the project area provide beneficial functions and values such as groundwater recharge, flood peak attenuation, floodwater storage, and wildlife corridors and habitat. For the proposed project, these functions would be impaired by construction and operation of the project. Staff and CDFG agree that acquisition and enhancement of off-site State waters would mitigate project impacts to jurisdictional waters. For the RSEP, staff and CDFG propose a mitigation ratio of 1:1 for all permanent and long-term impacts to waters of the State. Staff does not recommend compensatory mitigation for impacts to downstream reaches, because the hydrology and sand transport functions of the proposed redirected channels would largely replace function of the existing channel system (Appendix A).

The applicant has not proposed specific mitigation to reduce impacts to State waters during construction and operation of the proposed RSEP. Staff, in coordination with CDFG, proposes Condition of Certification **BIO-22**, and provides additional recommendations and guidance consistent with CDFG Streambed Alteration Agreement requirements. These include elimination of proposed detention basins at the southern margin of the project site to minimize alterations to off-site storm flows and sediment transport; implementation of Best Management Practices on-site during project construction and operation; and compensation for streambed impacts through the acquisition, protection, and management of comparable streambeds offsite at a ratio of 1:1 (i.e., one acres of streambed compensation for each acre impacted by the project).

It is possible that the applicant could meet the compensation requirements with the implementation of Condition of Certification **BIO-16**, which requires compensatory mitigation lands for desert tortoise habitat. With implementation of staff's proposed Condition of Certification **BIO-22**, impacts to State jurisdictional waters associated with the desert washes on the solar generator site, generator tie-line, and interconnector substation would be mitigated to less-than-significant levels under CEQA. This condition also fulfills requirements of CDFG's Lake and Streambed Alteration Agreement program pursuant to Fish and Game Code Section 1600 et seq. Because the construction of the RSEP would involve the diversion of offsite water around the site, and onsite runoff would be contained onsite (where it would evaporate or percolate to the groundwater), staff would require the applicant to restore flow across the project area upon the project's retirement. Staff concludes that these measures would reduce impacts of the solar generator, generator tie-line, and interconnector substation to state-jurisdictional streambeds below a level of significance by minimizing project impacts to streambeds; protecting sufficient off-site acreage to offset the on-site impacts; and reclaiming on-site

streambed upon eventual closure of the RSEP. Staff has not determined potential significance of project impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

Impacts During Operation

Operation of the RSEP would cause long-term persistent impacts to biological resources within the perimeter fence and in adjacent habitats surrounding the solar generator site, and along the length of the generator tie-line. Operational impacts to biological resources include disturbance to common and special-status wildlife from vehicle traffic; heliostat maintenance and washing; mowing; night-time lighting; maintenance activities; noise; collisions with structures; and the potential for electrocution and incineration of birds. The proposed evaporation ponds would also provide subsidies for ravens which can lead to increased tortoise predation. These impacts are discussed below. Operational impacts of the new fiber optic OPGW along the existing 161-kV Parker-Blythe transmission line would be minimal, because the new ground line would be placed on existing structures and would replace an existing ground line.

Operational Impacts: Vegetation

Ongoing disturbance, including mowing and other facilities operations and maintenance; increased shade from the heliostats; and increased dry-season water availability (from mirror washing) would all contribute to increased weed cover and abundance.

There is some evidence that locally dominant desert shrubs, including burrobush, creosote bush, and white bursage, will resprout vigorously following one mowing (CH2M Hill 2009). However, staff does not believe that this preliminary research provides useful information about the long-term effects of mowing on the project area's plant communities. Little research has been done on the longer-term effects of mowing on native desert plant species, but extensive studies have been conducted on general plant responses to short- and long-term mowing in weed research. Mowing suppresses vegetation through carbohydrate starvation, reduces its water use (which is likely to give a competitive edge to annual grasses between shrubs) and discourages reproduction by seed. Frequent mowing can stimulate branch development in some species, but would eventually deplete the plants' carbohydrate reserve if done often enough (Radosevich et al. 1997). Sprouting is a common morphological response and, when repeated, results in a prostrate, turf-like structure in adapted species. Mowing every few weeks for at least one or two seasons may be all that is required to suppress perennial vegetation (Radosevich et al. 1997).

Vegetation not cleared or mown for construction and maintenance could be indirectly impacted by increased shading from the heliostats, depending on its location. Shading would alter microclimate conditions, including soil temperatures and light availability for photosynthesis, altering habitat suitability for native species and likely enhancing suitability for invasive weeds. Further, if mown material is mulched on-site, the mulch would alter native soil characteristics by increasing organic matter, soil moisture, and mineral nutrients. These effects would likely favor invasive weed species adapted to disturbance and increased moisture and nutrient availability. The proliferation of non-native annual species has dramatically increased the fuel load and frequency of fire in

many desert ecosystems (Lovich & Bainbridge 1999). Unlike other ecosystems in California, fire was not an important natural disturbance in the deserts. Most native desert shrubs are poorly adapted to even low-intensity fires. The potential spread or proliferation of non-native annual grasses, combined with the proximity to ignition sources could increase the risk of fire, and the effects to these poorly-adapted desert communities would be harmful, particularly to cacti and most native shrub species. Burned creosote and other native shrubs are typically replaced by short-lived perennials and non-native grasses (Brown & Minnich 1986).

Other indirect effects on plant communities during operation include soil compaction, changes to the soil structure by use of dust suppressants, and changes in the distribution of precipitation falling on the solar field site. Precipitation runoff would concentrate along the driplines below the heliostats rather than being uniformly distributed, altering localized microhabitat, including erosion and soil water content. Mirror wash water would similarly concentrate along the drip line below the heliostats, causing minor erosion of the soil at the drip lines and promoting invasive weeds.

Energy Commission staff considers the direct and indirect impacts to native plant communities from operation of the project to be significant. Staff's proposed Condition of Certification **BIO-11**, the Weed Management Plan, would minimize the spread of non-native and invasive plant species on the site.

Indirect and Off-Site Operational Impacts To Special-status Plants, Vegetation and Habitat

Project operations have the potential to cause a variety of indirect effects to special status plants, native vegetation and wildlife habitat outside the project boundary. These include effects of erosion or sedimentation that could result from altered hydrology on the site (i.e., plants, their habitat, or their seed banks occurring down slope of disturbed soils could be eroded away or could be covered in sediment); changes in the hydrology from alterations in the drainage patterns of the site (e.g., to desert washes); the introduction of new weeds or spread of weeds already present in the area from the solar fields into the surrounding habitat; greater than normal dust levels; effects of herbicide drift on vegetation; and an increased risk of fire. Weeds, dust, and hydrology are discussed in greater detail above. These impacts would be similar to those described under indirect and off-site construction impacts to special status plants, vegetation and habitat. Staff's recommended Conditions of Certification **BIO-1** through **BIO-12**, and **BIO-16** would mitigate these impacts. Staff concludes that implementation of these measures would reduce indirect and off-site operational impacts to special status plants, native plant communities, and wildlife habitat to less than significant levels under CEQA by minimizing vegetation impacts to the extent practicable; revegetating temporarily disturbed areas; implementing a Worker Environmental Awareness Program; controlling dust and erosion; controlling invasive weeds and preventing infestations by newly introduced weeds; and providing for long-term conservation and management of native vegetation on desert tortoise compensation lands; and implementing a site closure plan.

Operational Impacts: Birds and Common Wildlife

Some bird species will likely nest in the project area both during construction and operation of the facility. Operational impacts are expected to remain an ongoing source of disturbance to nesting birds. As described above, operation of the facility would likely result in disturbance to both ground nesting birds and possibly to birds actively nesting on the structures.

Species that utilize the project site for foraging but not nesting, such as golden eagle and prairie falcon, and wintering birds such as merlins, sharp-shinned hawks, and ferruginous hawks would be affected by the loss of foraging habitat, which would be considered significant absent mitigation. Overall the loss of foraging habitat for these special-status bird species would add to the cumulative, significant loss of habitat for these species within the region. Staff's proposed Condition of Certification **BIO-16**, the compensatory mitigation plan for desert tortoise, would reduce this habitat loss below a level of significance by the preservation of similar foraging areas.

The size of the project coupled with the operations activities including vegetation management, mirror washing, and other heliostat maintenance, as well as operational noise levels, would cause ongoing disturbance and mortality to small mammals and reptiles within the project perimeter as well as birds in the area.

Operational Impacts: Ravens, Coyotes, and Other Predators

Human activities in the RSEP area could provide resources in the form of trash, litter, or water, which attract and subsidize unnaturally high numbers of predators such as the common raven, kit fox, and coyote. This influx of predators could then place unnaturally high predation pressure on desert tortoises and other special-status species in the region. For example, common raven populations in some areas of the Mojave Desert have increased 1,500% from 1968 to 1988 in response to expanding human use of the desert (Boarman 2002). Since ravens were scarce in this area prior to 1940, the current level of raven predation on juvenile desert tortoises is considered an unnatural occurrence (BLM 1990; USFWS 2008a). In addition to ravens, feral dogs have emerged as major predators of the tortoise. Dogs may range several miles into the desert and have been found digging up and killing desert tortoises (USFWS 1994b; Evans 2001). Dogs brought to the project site with visitors may harass, injure, or kill desert tortoises, particularly if allowed off leash to roam freely in occupied desert tortoise habitat. The worker environmental awareness training (Condition of Certification **BIO-6**) and restrictions on pets being brought to the site required of all personnel (Condition of Certification **BIO-8**) would reduce or eliminate the potential for these impacts. Construction and operation of the RSEP would increase raven and coyote presence in the project area. Ravens capitalize on human-related food and water "subsidies" and habitat changes to expand into areas where they were previously absent or in low abundance. Ravens were observed during staff's site visits of the RSEP site.

Ravens habituate to human activities and are subsidized by the food and water, as well as roosting and nesting resources that are introduced or augmented by human encroachment. Road killed animals, including small mammals and reptiles provide another attractant and subsidy for opportunistic predators and scavengers such as ravens. Ravens use transmission line structures as nest and perch sites, increasing the

potential for loss of tortoises from raven predation. Because of the agricultural and other land uses in the region, particularly near the Colorado River, ravens will continue to occur at elevated numbers.

Road kills would increase with increased RSEP construction and operations traffic, further exacerbating the raven/predator attractions and increasing desert tortoise predation levels. In addition, bird strikes that occur from either collision with facility structures or transmission lines may also attract ravens. There are numerous anthropogenic perch sites (e.g., power distribution lines, abandoned structures, and sign posts) and potential food subsidies (road killed animals and litter). Thus, tortoises in the RSEP area may already be subject to raven predation. Any cumulative loss of juvenile tortoises due to the further addition of raven subsidies could have a long-term effect on the tortoise population by reducing juvenile tortoise survivorship (Boarman 2003). The population-level consequences of this effect may not be apparent for years because tortoises do not typically reach sexual maturity until approximately 15 to 20 years of age.

To reduce the local impacts of increased raven presence at the RSEP site and ancillary facilities, the applicant has prepared a draft Raven Management Plan (Appendix B of CH2MHill 2010c) and has recommended additional avoidance and minimization measures. Staff has incorporated these recommendations into proposed Conditions of Certification **BIO-8** and **BIO-17**, which would minimize the effects of increased predation on desert tortoise in the project area. Staff also recommends participating in region-wide raven management (below).

Regional Approach to Raven Control

The USFWS, in cooperation with BLM, National Park Service, Department of Defense, and Department of Agriculture, has developed a comprehensive, regional raven management and monitoring program in the California Desert Conservation Area to address the regional, significant threat that increased numbers of common ravens pose to desert tortoise recovery efforts (USFWS 2010d). The Regional Raven Management Program will implement recommendations in the USFWS *Environmental Assessment to Implement a Desert Tortoise Recovery Plan Task: Reduce Common Raven Predation on the Desert Tortoise* (USFWS 2008b). To mitigate the RSEP's contribution to cumulative and indirect impacts on desert tortoise from raven predation, staff recommends that the applicant contribute toward implementation of the Regional Raven Management Program (USFWS 2010c), as described in staff's proposed Condition of Certification **BIO-17**. To mitigate for the regional effects of ravens on desert tortoise, the applicant shall provide a onetime fee in the amount of \$105.00 per acre to the REAT Account held by the National Fish and Wildlife Foundation (NFWF), for the 1,776-acre total project footprint area. This payment of \$190,209.60 would support the regional raven management plan activities focused within the Colorado Desert Recovery Unit. The fees contributed by the applicant would fund raven removal actions, education and outreach efforts, and surveying and monitoring activities identified in the federal Environmental Assessment (USFWS 2008b). Staff has concluded that that implementation of these actions would be an effective means of reducing the project's cumulative contributions to desert tortoise predation from increased raven numbers; would reduce the impacts below a level of significance; and, in combination with other

Conditions of Certificate described above, would satisfy the requirements for full mitigation pursuant to CESA.

Staff's recommended Condition of Certification **BIO-17** also would require the applicant to prepare and implement a Raven Monitoring, Management, and Control Plan for all project-related activities and components. The Plan would involve identifying and preventing conditions that might attract or support ravens (for example, eliminating food sources such as garbage or roadkill, and minimizing creation of structures that could provide raven perches, nests, or roosts), monitoring the effectiveness of raven management and control measures, and then implementing additional adaptive management measures to make sure that the project does not result in an increase in raven numbers. Staff concludes that implementation of measures in Condition of Certification **BIO-17** would avoid, minimize, or compensate for the project's potential contributions to increased desert tortoise predation from ravens to less than significant levels pursuant to CEQA and would fully mitigate these potential impacts pursuant to CESA.

Operational Impacts: Increased Risk from Roads/Traffic

Vehicle traffic would increase as a result of construction and improvement of access roads, increasing the risk of injuring or killing desert tortoise and other wildlife. Vehicle access by project personnel during operations, as well as by the public along the new generator tie-line access road and improved access along the existing 161-kV Parker-Blythe transmission line, could result in mortality of desert tortoises by vehicle strikes. The potential for increased traffic-related tortoise and other wildlife mortality is greatest along paved roads where vehicle frequency and speed is greatest, though animals on dirt roads may also be affected depending on vehicle frequency and speed. Data indicate that desert tortoise numbers decline as vehicle use increases (Bury et al. 1977) and that tortoise sign increases with increased distance from roads (Nicholson 1978; Karl 1989; von Seckendorf and Marlow 1997, 2002). Additional impacts that may occur from unauthorized use of the access roads in the project area include unauthorized trail creation. To minimize the risks of increased traffic fatality and other hazards associated with roads at the RSEP solar field site and ancillary facilities, the applicant has proposed a variety of minimization measures which staff has incorporated into Condition of Certification **BIO-8**. These measures include confining vehicular traffic to and from the project site to existing routes of travel, prohibiting cross country vehicle and equipment use outside designated work areas, and imposing a speed limit of 20 miles per hour on access routes other than SR-62. In addition, staff's recommended Conditions of Certification **BIO-16** requires compensation mitigation at a 3:1 ratio for habitat impacts on the new generator tie-line alignment. This increased ratio is intended, among other things, to mitigate for potential vehicle strikes along the alignment by protecting and enhancing off-site at a ratio greater than 1:1.

Operational Impacts: Noise, Disturbance, and Lighting

Increased noise and other adverse project effects to wildlife habitat on the project site would be mitigated below a level of significance through measures described elsewhere in this section of the SA/DEIS. The effects of operational noise on wildlife and habitat surrounding the site are addressed here. Noise may affect birds and other wildlife in several ways, as described above under **Construction Impacts to Common Wildlife**

and Habitat. During operations, estimated noise levels at the solar generator's perimeter fence would range between about 43 and 52 dBA (SR 2009a, including Fig. 5.7-1). These levels are roughly comparable to light traffic or rainfall noise (SR 2009a) but may be loud enough to adversely affect bird nesting success. For most common species, staff concludes that this impact would be less than significant, but staff believes that it could significantly affect breeding habitat suitability for special status desert upland passerine birds. Staff's proposed Condition of Certification **BIO-16** (Desert Tortoise Compensatory Mitigation) would require habitat compensation habitat for impacts to desert tortoise habitat on the site. This compensation land also would serve as habitat for upland bird species, including loggerhead shrike and others that may be affected by the project. If the applicant elects to use lands surrounding the solar generator site as compensation habitat, the lands within a 250-foot radius of the project area would be credited at a reduced ratio of 0.5:1 due in part to their noise-related reduced habitat value. Staff concludes that **BIO-16** would reduce potentially significant operational impacts of noise below a level of significance by protecting off-site lands.

Lighting may affect essential behavioral activities, physiology, population ecology, and ecosystems of diurnal, crepuscular, and nocturnal wildlife, and ecological light pollution may affect competition and predation for some species (Longcore and Rich 2004). Lighting may also increase the risk of predation of wildlife because they may be more detectable to nocturnal predators (USACE and CDFG 2009). Many insects are drawn to lights, and species that prey on insects, such as bats, may be attracted to lighted construction areas which would increase the potential for disturbance and mortality. However, studies have indicated that many small species, such as rodents, rabbits, snakes, and bats, actually forage at lower rates at high illumination levels (Longcore and Rich 2004), which may be a biological adaptation to high levels of moonlight. Overall, chronic ecological light pollution may favor light-tolerant species over those that are dark-adapted (Longcore and Rich 2004).

The operation of the RSEP would require on-site nighttime lighting for safety and security, which could disturb nocturnal wildlife. In addition, the large scale maintenance activities would require vehicle and equipment lighting in order to safely clean and service the heliostats. To reduce off-site lighting impacts, lighting at the RSEP facility would be restricted to areas required for safety, security, and operation. Exterior lights would be hooded, and lights would be directed on site so that light or glare would be minimized. Low-pressure sodium lamps and fixtures of a non-glare type would be specified. Switched lighting would be provided for areas where continuous lighting is not required for normal operation, safety, or security; this would allow these areas to remain un-illuminated (dark) most of the time, thereby minimizing the amount of lighting potentially visible off site. These measures are described in staff's proposed Condition of Certification **VIS-2**. With implementation of this measure, lighting impacts to wildlife at the RSEP would be reduced to less-than-significant levels under CEQA.

Operational Impacts: Evaporation Ponds

The proposed RSEP includes three five-acre evaporation ponds that would process wastewater discharge from the water treatment system and oil/water separator (SR 2009a). Staff presumes that one or more of these ponds would hold surface water year-around. Evaporation ponds could serve as a perennial water source in an otherwise arid

region and act as a subsidy to ravens. Even if they are fenced off from wildlife, evaporation ponds may still attract predators and other species, including waterfowl. Subsidized predators would increase potential project effects to desert tortoise, Mojave fringe-toed lizard, and other less mobile species. In addition, small mammals, waterfowl, shorebirds, and other resident or migratory birds that drink or forage at the ponds would be exposed to potentially lethal doses of hyper-saline water, depending on the salts and concentrations present. Monitoring results from the summer of 2007 at Harper Lake Solar Electric Generating System in the Mojave Desert revealed that numerous waterfowl died at the evaporation ponds due to salt toxicosis (Luz 2007). Another concern is that the evaporation ponds would attract foraging birds, whether or not they land on the ponds, increasing potential risk of burning near the central tower or standby points, or collision with project facilities including the proposed transmission towers, heliostat structures, and central tower. Foraging bats also may be attracted to the evaporation ponds, but staff believes that potential adverse impacts to bats would be minimal because they would not be active during daylight hours while the heliostats focus energy on the central tower.

The applicant has proposed measures to reduce or avoid impacts of the ponds to wildlife, including monitoring the ponds during operation to determine usage and any injury, mortality, or deformities associated with birds at the ponds. The applicant indicated that corrective measures would be implemented if mortality was attributed to salt toxicosis or encrustation (SR 2009a). These measures could include the use of an air canon, Bird-B-Gone Balloon (visual scare device), or other hazing device to scare birds away from the site (Appendix 5.15B of SR 2009a).

The applicant also indicated that the ponds would be designed to minimize wildlife use and would include features such as 33 percent slopes on the interior walls of the ponds and anti-perching devices around the perimeters of the ponds, both of which are expected to minimize access to the water by birds and other wildlife (Appendix 5.15B of SR 2009a). However, the applicant proposes to keep the ponds uncovered to maximize evaporation and avoid trapping birds under netting or monofilament arrays; this would allow birds to access the evaporation ponds by landing on the water (Appendix 5.15B of SR 2009a). The primary risks to birds associated with the evaporation ponds are salt encrustation and salt toxicosis. High levels of salt in the water in the ponds can result in the precipitation of salt into crystals, which can form and accumulate on feathers and interfere with flight. Salt toxicosis (poisoning) can also result (Appendix 5.15B of SR 2009a). Terrestrial wildlife are at risk of drowning if they fall into the water and cannot climb back out, and they can be poisoned by high levels of salt and other toxins or impurities in the water of the evaporation ponds. However, terrestrial wildlife exposure to the evaporation ponds would be limited by the perimeter exclusion fencing, and any individuals that could encounter the ponds would likely be those that remain within the fence line after the fence is erected at the start of construction activities. Staff considers potential impacts to wildlife to be significant absent mitigation under CEQA. To reduce these impacts, staff recommends that the applicant cover the ponds with netting or other suitable materials to minimize bird mortality, and prepare and implement an Evaporation Pond Design, Monitoring, and Management Plan. This plan would incorporate any revisions to pond size or design discussed in the Soil and Water section of the SA/DEIS and would require the review and approval by USFWS, CDFG, and staff. The plan would include language specifying the type of netting and fencing to be

used, reporting protocols and remedial actions required in the event of bird mortality. The plan would be developed and implemented per guidance in staff's proposed Condition of Certification **BIO-24** (Evaporation Pond Design, Monitoring, and Management Plan). Staff concludes that implementation of recommended design modifications and follow-up monitoring and management, as required by this Condition of Certification would reduce evaporation pond impacts to birds and other wildlife to less-than-significant levels under CEQA.

Operational Impacts: Wildlife Movement

Potential wildlife movement routes through the area are described above (**Impacts to Wildlife Movement**). This subsection is based on that analysis, but addresses the proposed project's operational impacts to wildlife movement, and only those that are distinct from construction impacts described above. The primary difference between anticipated construction impacts and operational impacts to wildlife movement will be the removal of the security fence around the proposed logistics and laydown area at the northern site boundary, along SR-62. After construction is completed, the proposed RSEP would be surrounded by a circular security and tortoise exclusion fence that would effectively exclude terrestrial wildlife movement onto or across the site. The circular exclusion fence would reduce potential north-south wildlife movement at the two desert wash crossings north of the site.

At the two points where washes cross SR-62 near the project site, the perimeter exclusion fence would be several hundred feet or more south of the highway and its outline would tend to direct southward-traveling wildlife to the east or west, away from the highway and the RSEP site (CH2MHill 2010a: Fig. DR59-1). At these two sites, the fence would not be immediately adjacent to the highway and thus would not force animals to travel along the roadway for any distance. Therefore, wildlife moving southward through those crossings would likely be at increased risk of road mortality compared with present conditions, though somewhat decreased risk compared with conditions during the construction phase of the project. This risk is somewhat reduced by the proposed configuration of the permanent fence.

Staff believes that numerous species, including large mammals (burro deer, Nelson's bighorn sheep, and mountain lion) and perhaps desert tortoises, may infrequently cross the three linear barriers north of the proposed RSEP site. The proposed project, including the permanent perimeter fence, would further limit potential movement. However, due to presence of numerous similar crossing sites to the east and west, and due to the proposed configuration of the perimeter fence, staff concludes that the proposed project's operational impacts to wildlife movement would be less than significant. However, in order to minimize highway mortality, staff recommends Condition of Certification **BIO-21**, Fence Locations: Logistics, Lay-down Area, and Access Road. This condition would require that the logistics and lay-down area be redesigned to provide a 100-foot buffer area between the road shoulder and the temporary security fence, and that the security gate on the main access road be relocated to the main fenceline, to remove the fenced barrier to east-west wildlife movement across the permanent access road.

Operational Impacts: Avian Collision, Incineration, Electrocution, Glare, Lighting

In addition to the adverse impacts of lost or degraded habitat, the proposed RSEP would cause operational impacts to migratory and special-status bird species, including mortality caused by collisions with the proposed tower, heliostats, or transmission line; incineration or burns to birds that fly into the reflected sunlight between the heliostats and the solar receiver tower; and potential adverse effects of glare.

Collision and Incineration

Bird mortality due to collision with heliostats and the solar receiver tower, and by burning when flying through “standby points” were documented by McCrary et al. (1986) for the 10-megawatt Solar One facility east of Daggett, San Bernardino County, California. The standby points are the focal points in the air adjacent to the solar concentrator tower target, on which groups of heliostats may be focused when they are not stowed and when the power plant is on standby mode and not generating electricity (CH2MHill 2010a). The Solar One facility consisted of a 32-hectare (79-acre) heliostat field and 86-meter (282-foot) solar receiver tower. The researchers documented 70 bird fatalities during the course of a 40-week study, and estimated that about 10 to 30 percent of bird carcasses went undocumented because animal scavengers removed them before researchers detected them. The bulk of bird mortality (more than 75 percent) resulted from collisions with the heliostat mirrors. One known mortality resulted from collision with the solar receiver tower. Thirteen mortalities (19 percent) resulted from burns, apparently while flying through standby points.

The proposed RSEP would consist of a 1,410-acre facility including a 653-foot-tall solar receiver tower. By extrapolating from the Solar One data, staff estimates that the proposed RSEP, a much larger facility, could cause approximately 1,700 bird mortalities per year from collisions with heliostats and the solar receiver tower and burning as birds fly through concentrated solar energy near the solar receiver tower or standby points. However, at the Solar One facility, McCrary et al. (1986) speculated that bird mortality was largely due to large on-site evaporation ponds and surrounding agricultural land uses. Both these features produce insects in large numbers and attract feeding birds. While the proposed RSEP does include evaporation ponds, there is no adjacent agricultural land. The nearby Colorado River Aqueduct may be an attractant for birds or insects, though the Aqueduct has no adjacent riparian vegetation and contains swiftly moving water, and consequently would not be as strong an attractant as would a natural riparian feature.

Additional factors that may lead to mortality of migratory birds and special-status birds are nighttime project lighting, evaporation ponds, and perhaps a “mirage” effect that may be caused by the proposed heliostat field. Any of these could attract birds or bats to the facility, where they would be susceptible to mortality by collision or burning, as described above.

Most diurnal bird collisions with tall structures are associated with guyed towers in poor visibility conditions such as fog or inclement weather (Manville 2001). The RSEP does not include guyed towers or structures, and rarely is subject to weather that would reduce visibility. Thus, staff believes that nocturnal collisions with the tower are more likely to cause bird mortality than diurnal collisions. Lighting plays a substantial role in

collision risk because lights can attract nocturnal migrant songbirds. Major bird kill events have been reported at lighted communications towers (Manville 2001), with most kills resulting from towers taller than 300 to 500 feet (Kerlinger 2004).

The proposed transmission line and structures pose a collision threat to birds along the 10-mile generator tie-line corridor. Bird collisions with power lines generally occur when a power line or other aerial structure transects a daily flight path used by a concentration of birds, or migrants are traveling at reduced altitudes and encounter tall structures in their path (Brown 1993). Collisions are more probable near wetlands, valleys that are bisected by power lines, and within narrow passes where power lines run perpendicular to flight paths. Passerines (e.g., songbirds) and waterfowl (e.g., ducks) collide with wires (APLIC 1994, 2006), particularly during nocturnal migrations or poor weather (Avery et al. 1978). Overall bird densities in the project area are relatively low, but the Colorado River Valley is an important migratory route for many species. Some species tend to migrate along the river and focus primarily on wetlands habitats, but others migrate more broadly throughout the region (Rosenberg et al. 1991). Migratory or wintering species may travel through the Rice Valley en route between productive wetlands habitats at the Colorado River and elsewhere, such as the Iron Mountain area northwest of the project site. Staff concludes that the potential for bird mortality through collision with the proposed power line would be significant. Staff's proposed Condition of Certification **BIO-8** requires the applicant to construct the transmission line according to the standards in the Avian Power Line Interaction Committee's (APLIC's) *Mitigating Bird Collisions with Power Lines* (APLIC 1994) to minimize risk of collision. Staff's recommended Condition of Certification **BIO-25** (Avian and Bat Protection Plan and Monitoring Operational Impacts of Solar Collector on Birds) would require that the project owner prepare and implement an Avian Protection Plan to minimize death and injury of birds from collisions with facility features and focused heat and light at and near the central tower and at "standby points"; and to identify adaptive management measures to minimize such impacts. Further, the Avian Protection Plan shall provide documentation that the project is in compliance with the Bald and Golden Eagle Protection Act (Title 16, United States Code, section 668). With the implementation of this mitigation, impacts to birds from collisions with the proposed transmission line would be less than significant under CEQA.

Available data confirm that avian mortality has resulted from similar, much smaller solar facilities. Staff expects that bird mortality also will result from the proposed RSEP. Given the limited research-based data on these impacts, staff cannot conclude that they are significant. However, due to the potential for significant impacts, staff recommends monitoring so that if impacts do occur, they can be evaluated and addressed. In Condition of Certification **BIO-25** (Avian and Bat Protection Plan and Monitoring Operational Impacts of Solar Collection Facility on Birds and Bats), staff recommends that the applicant prepare and implement a formal long-term study to determine the effects of the proposed project on migratory and special status bird species, patterned after the McCrary et al. (1986) study and, if a significant level of bird mortality occurs during operation of the RSEP, the applicant shall adopt one or more adaptive management measures as recommended in the Condition of Certification.

Many of the avian fatalities at communications towers and other tall structures have been associated with steady-burning, red incandescent L-810 lights used on structures

for aircraft avoidance, which seem to attract birds (Gehring et al. 2009). Longcore et al. (2008) concluded that strobe or flashing lights on towers resulted in less bird aggregation, and, by extension, lower bird mortality, than steady burning lights.

To minimize this risk of collision and disturbance to wildlife from lights, staff recommends implementation of staff's proposed Condition of Certification **BIO-8**, which includes specifications that the lighting atop the towers use flashing strobe lights rather than steady burning, and recommendations for other project lighting to be shielded downward and turned off when not needed.

Electrocution

Egrets, herons, raptors, and other large aerial perching birds, including those accorded state and/or federal protection, are susceptible to power line electrocution if they simultaneously contact two energized phase conductors or an energized conductor and grounded hardware. This happens most frequently when a bird attempts to perch on a tower/pole with insufficient clearance between these energized elements. The majority of bird electrocutions are caused by lines that are energized at voltage levels between 1-kV and 60-kV, which generally have less clearance between these elements. Distribution lines designed for 69 kV or less represent a greater danger to raptors than transmission lines designed for greater than 69 kV, because the spacing between elements in distribution lines is much less than that of transmission lines (APLIC 2006). The RSEP proposed transmission line would be built to 230-kV standards to allow for future system upgrades, but would initially be energized at 161 kV (SR 2009a).

The BLM will not approve a transmission line that is not raptor safe. Potential impacts to wildlife resulting from electrocution by transmission lines required for RSEP interconnection may be mitigated by incorporating the construction design recommendations provided in *Suggested Practices for Raptor Protection on Power Lines: The State of the Art in 2006* (APLIC 2006). Specifically, the phase conductors shall be separated by a minimum of 60 inches and bird perch diverters and/or specifically designed avian protection materials should be used to cover electrical equipment where adequate separation is not feasible (APLIC 2006). This is further described in staff's proposed Condition of Certification **BIO-8** (Impact Avoidance and Minimization Measures); implementation of Condition of Certification **BIO-8** would prevent or minimize bird electrocution. With this proposed mitigation, staff concludes that the proposed transmission lines would not pose a substantial threat to birds and impacts would be less than significant under CEQA.

Glare

Glare from the reflection of sunlight off the heliostats is another factor that may contribute to the risk of avian collision on the project site. To date little is known regarding the avian response to glare from solar technology. However, it is likely that glare will affect birds to some degree. In the same way that large mirrored buildings may be confused by birds as open sky; the mirrors will reflect light and take on the color of the image being reflected. This may result in birds confusing the heliostats as either open sky or water which could increase the collision risk. Another factor that must be considered is how reflected light may result in damage to a bird's vision from direct exposure to high levels of photon flux density (PFD). Exposure to high intensity light or glare can damage vision and impair foraging in some species. The proposed heliostats

are sources of bright light caused from the diffuse reflection of the sun. Glint and glare studies of solar trough technology found that pedestrians standing within 20 meters (60 feet) of the perimeter fence when the mirrors rotate from the stowed position to a vertical position may see a light intensity equal to or greater than levels considered safe for the human retina (URS 2008). Staff concludes that any wildlife on a distance of 20 meters (66 feet) or closer could experience similar hazards from unsafe light intensity.

Bird response to glare from the proposed heliostats is not well understood. Given the lack of research-based data on these impacts, staff cannot reach a conclusion as to significance. However, due to potential for significant impacts, staff recommends monitoring bird mortality so that if impacts do occur, they can be addressed (refer to Condition of Certification **BIO-25** [Avian and Bat Protection Plan / Monitoring Operational Impacts of Solar Collection Facility on Birds and Bats]). The proposed monitoring program would be unable to distinguish mortality due to glare from other causes, but it would detect increased mortality levels and establish thresholds for implementing adaptive management measures to reduce mortality. Staff concludes that implementing BIO-25 would reduce any significant project effects to bird mortality below a level of significance by developing and implementing adaptive management measures to reduce mortality as indicated by monitoring.

Lighting

For birds, lighting plays a significant role in collision risk with tall towers because lights can attract nocturnal migrant birds, and major bird kill events have been reported at lighted communications towers (Manville 2001), with most kills from towers higher than 300 to 500 feet (Kerlinger 2004). Increased lighting during low-light periods can cause some species to leave the area and can disrupt foraging, breeding, or other activities. Lighting may disturb the nighttime rest and sleep periods of diurnal species, including most passerine birds, having similar effects as noise, including annoying individuals and causing them to abandon nests that are otherwise suitable (USACE and CDFG 2009). Nest site selection by some birds may also be affected by light, with nests being established farther from light sources (Longcore and Rich 2004). Staff has proposed measures to reduce the effects of operational lighting on birds, including designing facility lighting to prevent side casting towards adjacent habitat and using only flashing or strobe lights on project features that require lights per FAA regulations (Condition of Certification **BIO-8**). Implementation of these measures would reduce impacts to birds from facility lighting to less than significant under CEQA.

Operational Impacts: Waters of the State

Operational impacts to jurisdictional waters would include routine mowing of vegetation, vehicle access, interruption of natural flows by diversion channels and other project features, and repair of damaged culverts and roads following large storm events. Operation and maintenance of the heliostat mirrors would require vehicle access to wash the mirrors on a regular basis. Less frequent access would be necessary for maintenance and vegetation clearing or cropping. These activities would involve driving through existing drainages and also through drainages that have reformed due to natural processes (SR 2009a). These operational impacts would take place in jurisdictional waters already impacted during project construction. Staff's recommended mitigation for construction impacts, described above, are Conditions of Certification

BIO-16 (Desert Tortoise Compensatory Mitigation), and **BIO-22** (Streambed Impact Minimization and Compensation Measures). These conditions would also serve to mitigate operational impacts to waters of the state below a level of significance.

Project Closure and Decommissioning

In the future, the RSEP would experience either a planned closure or be unexpectedly (either temporarily or permanently) closed. When facility closure occurs, it must be done so that it protects the environment and public health and safety. A closure plan would be prepared by the project owner prior to any planned closure. To address unanticipated facility closure, an “on-site contingency plan” would be developed by the project owner and approved by the Energy Commission Compliance Project Manager (CPM). Facility closure requirements are discussed in more detail in the **General Conditions** section of this SA/DEIS. Facility closure mitigation measures would also be included in the Biological Resources Mitigation Implementation and Monitoring Plan (BRMIMP) prepared by the project owner and described in staff’s proposed Condition of Certification **BIO-7**.

The facility closure plan should address habitat restoration measures to be implemented in the event of a planned or an unexpected permanent closure and must also include a funding mechanism to ensure sufficient funds are available for decommissioning and habitat restoration. Planned or unexpected permanent facility closure should address the removal of the transmission conductors and poles since birds are known to collide with transmission line ground wires and poles may serve as predatory perches and nesting sites.

REDUCED ACREAGE ALTERNATIVE

The Reduced Acreage Alternative would be 7.2 percent smaller than the proposed project. It would be located in the same 2,560-acre square-shaped parcel within the larger 3,324-acre ownership property as the proposed project. Although the overall heliostat field distance from the central tower would be reduced, the number of heliostats would remain the same. The solar generator site would occupy about 1,270 acres instead of the 1,410 acres required for the proposed project. The solar receiver tower location would remain the same, with the edges of the field contracting towards the center. The heliostat footprint of the Reduced Acreage Alternative is shown in **Alternatives Figure 2**. The site layout, 653-foot total height of the solar tower and receiver, and transmission interconnection to Western’s Parker-Blythe transmission line would be the same as the proposed project. The generation output would be reduced by approximately 2 MW.

Similar to the proposed project, the Reduced Acreage Alternative would transmit power to the grid through the planned Western substation to be located adjacent to Western’s Parker Blythe 161-kV transmission line.

The Reduced Acreage Alternative is evaluated in this SA/DEIS because it would reduce the proposed project footprint by about 140 acres, reducing impacts to the most active ephemeral washes on-site (i.e., washes downstream from the blueline channel on the eastern margin of the site), habitat for the State and federally listed threatened desert

tortoise, and impacts to the historic Rice airfield. The Reduced Acreage Alternative achieves the project's energy production objective, while marginally reducing impacts to the desert environment. A limited acreage alternative was suggested in scoping comments.

SETTING AND EXISTING CONDITIONS

The setting for the Reduced Acreage Alternative is the same as described above for the proposed project. All project elements, including number of heliostats, evaporation ponds, generator tie-line, etc. would be as described for the proposed project, above. Because the footprint of the Reduced Acreage Alternative is located entirely within the footprint of the proposed project, the environmental setting with regard to biological resources would be the same. Please see the discussion of existing conditions under Section C.2.5.1.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

The Reduced Acreage Alternative would decrease the project footprint by approximately 140 acres, or approximately ten percent. The boundary of the solar field site would contract slightly towards the center as compared with the proposed project. This altered project design would avoid impacts to the most active ephemeral washes, in the eastern margin of the site. Otherwise, the design change would not alter project impacts to biological resources. This reduction in project size would not avoid desert tortoise impacts, though it would reduce habitat loss by approximately 140 acres. Avoidance of the easternmost ephemeral washes would slightly reduce impacts to waters of the State and would reduce or avoid alterations to existing active flood flow and sediment transport downslope across the site. Impacts to biological resources under the Reduced Acreage Alternative would be similar to those described for the proposed project (see Section C.2.5.2), except for the reduction in acreage of impacts to common and special status species, including desert tortoises, golden eagle foraging habitat, and others as described above.

Staff's proposed conditions of certification would mitigate for the Reduced Acreage Alternative's direct, indirect, and cumulative impacts to biological resources. These conditions are identical to those for the proposed project, except that the compensatory mitigation acreages recommended for desert tortoise habitat (Condition of Certification **BIO-16**) and State waters (Condition of Certification **BIO-22**) would be adjusted to reflect the reduced project footprint.

NORTH OF DESERT CENTER ALTERNATIVE

The North of Desert Center Alternative would be a 150 MW solar thermal facility located on approximately 2,643 acres of land. It is located along Desert Center Rice Road (State Route 177) east of Kaiser Road, north of Oasis Road, and approximately 1.6 miles north of I-10. The North of Desert Center Alternative is primarily private land with smaller parcels of BLM land in the eastern portion of the site. It is largely fallow agricultural land. The existing SCE 161-kV transmission line (from the Blythe-2 substation to the Eagle Mountain-1 substation) that traverses the alternative site would be realigned to roughly follow the site boundary. A new 0.125-mile transmission line

(along Osborne Ave.) and substation would interconnect to the realigned SCE line at the northeast boundary of the site. The boundaries and transmission realignment of the North of Desert Center Alternative are illustrated in **Alternatives Figure 2**.

The Desert Center Alternative is evaluated in this SA/DEIS because it would reduce impacts to cultural resources; the RSEP is located on the historic Rice Army Airfield. The North of Desert Center Alternative would allow the applicant to contribute clean, renewable energy to help meet the State's energy goals, while minimizing impacts to the desert environment.

SETTING AND EXISTING CONDITIONS

The North of Desert Center Alternative site is located north of Interstate-10, and west of Rice Road (SR 177). Most of the site is private agricultural land. A portion of the North of Desert Center Alternative site is public land managed by BLM.

The North of Desert Center alternative site is located in the Colorado Desert Bioregion, described for the proposed project site, in Section C.2.5.1.

The North of Desert Center Alternative site consists mostly of fallow agricultural fields and some active orchards. The Rice Road traverses the east side of the site, just outside the site boundary. Surrounding lands to the north, east, and west are mostly undeveloped BLM land, and to the south are private lands that make up Desert Center including the Desert Center Airport and the newly constructed Chuckwalla Valley Racetrack, along with rural residences. The dry McCoy Wash is located southwest of the northern and eastern portions and northwest of the southern portion of the Desert Center Alternative site. Topography on the North of Desert Center Alternative site is relatively flat, with elevation ranging from approximately 340 to 570 feet above mean sea level, from the south to the north. Soils mapped for the North of Desert Center Alternative site are comprised primarily of three soil series: Rositas, Orita, and Aco; most of which is classified as prime farmland. Other soil series mapped for the North of Desert Center Alternative site include Carrizo, Valva, Quilotosa, Hyder, Cipriano, and Cherioni (BLM and CEC 2010b).

One major wash supporting desert dry wash woodland passes through the fallow agricultural lands in the north-central portion of the North of Desert Center Alternative site. Additionally, an area south of the large wash, supporting Sonoran creosote bush scrub but no riparian or desert wash vegetation, shows evidence of some surface water flow. However, the area is surrounded on three sides by fallow agricultural fields (the fourth side is adjacent to the wash), and the flow appears to be historic (possibly an artifact of past irrigation). The first wash would be considered waters of the State, under the jurisdiction of the CDFG but the second one may not be. A jurisdictional delineation would be necessary to confirm this. Both washes could be waters of the U.S. under the jurisdiction of the USACE, dependent upon USACE interpretation of its watershed jurisdiction. However, based on review of regional aerial photography, neither wash appears to be a tributary to waters of the U.S. A letter of concurrence from the USACE would be necessary to confirm this conclusion. Because the North of Desert Center Alternative site is larger than the footprint required for the project, the large wash could be avoided when siting the facility.

Undisturbed portions of the North of Desert Center Alternative site were observed being used, directly or via sign, by common animal species such as coyote, black-tailed jackrabbit, white-crowned sparrow (*Zonotrichia leucophrys*), northern flicker (*Colaptes auratus*), Say's phoebe (*Sayornis saya*), and kangaroo rat. Little wildlife use was noted in areas supporting fallow agriculture.

The large wash supporting desert dry wash woodland (above) may provide for wildlife movement across the site through the fallow agricultural lands to the east and west connecting undeveloped or undisturbed lands on either side of the North of Desert Center Alternative site.

Vegetation Communities. Fallow agriculture, Sonoran creosote bush scrub, desert saltbush scrub, and desert dry wash woodland are the four primary vegetation communities on the North of Desert Center Alternative site. Some active agriculture and developed land is also present.

Fallow agriculture covers approximately 3,750 to 4,250 acres (approximately 63 to 71 percent) of the North of Desert Center Alternative site. Visible furrows and irrigation tubing are still present. This fallow land supports very sparse growth of creosote bush (*Larrea tridentata*), along with a few persisting jojoba (*Simmondsia chinensis*), which may have been the plant being farmed. Dead jojoba plants are common throughout the area. Among the sparsely growing shrubs, minimal cover of annual species such as Mediterranean grass (*Schismus* sp.; a non-native species), cryptantha (*Cryptantha* spp.), and desert sunflower (*Geraea canescens*) are present.

Sonoran creosote bush scrub occurs on approximately 1,100 to 1,600 acres in the central and western portions of the North of Desert Center Alternative site and supports varying densities of creosote bush and desert saltbush (*Atriplex polycarpa*) as well as sparse to moderate cover of annual plant species such as desert Indian wheat (*Plantago ovata*), cryptantha, and Mediterranean grass.

Desert saltbush scrub occurs on approximately 140 to 240 acres of the northeastern portion of the North of Desert Center Alternative site and is dominated by desert saltbush with an occasional creosote bush. Mediterranean grass is common in the open areas between shrubs.

Desert dry wash woodland occurs on approximately 180 to 280 acres in the large wash that passes through the north-central portion of the North of Desert Center Alternative site. This community is dominated by blue palo verde (*Cercidium floridum*), desert ironwood (*Olneya tesota*), creosote bush, and desert saltbush and supports a number of annual plant species such as cryptantha, phacelia (*Phacelia* spp.), Mediterranean grass, devil's lantern (*Oenothera deltoides*), desert Indian wheat, and browneyes (*Camissonia claviformis*).

Special-status species observations have been reported to the CNDDDB within 5 miles of the North of Desert Center Alternative site (**Biological Resources Table 5**). These CNDDDB records include one listed plant species, the federally endangered Coachella Valley milk-vetch and one federally and state listed reptile, the desert tortoise (CDFG 2010a). The CNDDDB includes a record of the desert tortoise approximately 3,500 feet

northeast of the North of Desert Center Alternative site on National Park Service land, and designated critical habitat for the desert tortoise is located approximately 0.9 mile west of the North of Desert Center Alternative site (USFWS 1994a).

**Biological Resources Table 5
California Natural Diversity Database Records for Special-Status Species
within Five Miles of the North of Desert Center Alternative Site**

Common Name <i>Scientific Name</i>	Status State/Fed/CNPS/BLM	Occurrence Within 5 Miles of North of Desert Center Alternative Site
PLANTS		

Common Name Scientific Name	Status State/Fed/CNPS/BLM	Occurrence Within 5 Miles of North of Desert Center Alternative Site
Chaparral sand-verbena <i>Abronia villosa</i> var. <i>aurita</i>	--/--/List 1B.1/--	Reported approximately 2 to 3 miles southwest of the site.
Harwood's milk-vetch <i>Astragalus insularis</i> var. <i>harwoodii</i>	--/--/List 2.2/--	Reported approximately 4 miles south of the site.
Coachella Valley milk-vetch <i>Astragalus lentiginosus</i> var. <i>coachellae</i>	--/FE/List 1B.2/--	Reported on site in 1998 along Desert Center Rice Road (State Route 177), approximately 1.3 miles east of the site. Also reported approximately 4.5 miles northeast of site in 1973.
Emory's crucifixion thorn <i>Castela emoryi</i>	--/--/List 2.3/--	Reported in the westernmost portion of the site in 1996.
Las Animas colubrina <i>Colubrina californica</i>	--/--/List 2.3/--	Reported from approximately 3.5 to 4.5 miles west of the site, approximately 5 miles northwest of the site, and approximately 4.6 miles south of the site.
Alverson's foxtail cactus <i>Coryphantha alversonii</i>	--/--/List 4.3/--	Multiple records within 5 miles of site, including approximately 1 mile west of the site, approximately 3.4 miles southwest of the site, approximately 4 miles northwest of the site, and approximately 3 miles southeast of the site.
California ditaxis <i>Ditaxis serrata</i> var. <i>californica</i>	--/--/List 3.2/--	Reported approximately 4 miles southwest of the site and approximately 4.6 miles northwest of the site.
Orocopia sage <i>Salvia gregatae</i>	--/--/List 1B.3/--	Reported approximately 5 miles south of the site.
Cove's cassia <i>Senna covesii</i>	--/--/List 2.2/--	Reported approximately 4 miles northwest of the site. Alternative site may be too low in elevation for this species.
ANIMALS		
Prairie falcon <i>Falco mexicanus</i>	CDFG WL/--/--	Reported approximately 2 to 3 miles west of the site and approximately 0.75 mile northeast of the site.
Desert tortoise <i>Gopherus agassizii</i>	ST/FT/--/S	Reported adjacent to or within the northern and eastern portion of the site as well as approximately 4.7 miles southwest, approximately 4.6 miles west, approximately 4 miles northwest, and approximately 5 miles north of the site.
Nelson's bighorn sheep <i>Ovis canadensis nelsoni</i>	--/--/--/S	Reported approximately 3.5 miles northwest of the site and 2.5 miles northeast of the site.
Bendire's thrasher <i>Toxostoma bendirei</i>	CSSC/--/--/S	Reported approximately 3 miles south of site in 2004.
LeConte's thrasher <i>Toxostoma lecontei</i>	CDFG WL/--/--/S	Reported approximately 3 miles south of site and approximately 4 miles southwest of the site in 2004.

Status Codes:

Federal FE - Federally listed endangered: species in danger of extinction throughout a significant portion of its range
 FT - Federally listed threatened: species likely to become endangered within the foreseeable future

State SE - State listed endangered
 ST = State listed threatened
 CSSC = Species of special concern

California Native Plant Society (CNPS)

List 1B - Rare, threatened, or endangered in California and elsewhere

List 2 - Rare, threatened, or endangered in California but more common elsewhere

List 3 - Plants which need more information

List 4 - Limited distribution – a watch list

0.1 - Seriously threatened in California (high degree/immediacy of threat)

0.2 - Fairly threatened in California (moderate degree/immediacy of threat)

0.3 - Not very threatened in California (low degree/immediacy of threats or no current threats known)

U.S. Bureau of Land Management (BLM)

S = Sensitive

BLM Manual § 6840 defines sensitive species as "...those species that are (1) under status review by the FWS/NMFS; or (2) whose numbers are declining so rapidly that federal listing may become necessary, or (3) with typically small and widely dispersed populations; or (4) those inhabiting ecological refugia or other specialized or unique habitats." <www.blm.gov/ca/pdfs/pa_pdfs/biology_pdfs/SensitiveAnimals.pdf>

The primary species of concern at the North of Desert Center Alternative site is the federal and State listed threatened desert tortoise. The desert tortoise has a high potential to occur in Sonoran creosote bush scrub habitat in the southwestern portion of the North of Desert Center Alternative site. This habitat area is adjacent to and biologically connected to more undisturbed habitat to the west and ultimately to desert tortoise critical habitat that is approximately 0.9 mile west of the North of Desert Center Alternative site (USFWS 1994a). There is no agricultural land or other disturbance or impediment to movement between the habitat area on the North of Desert Center Alternative site and the designated critical habitat. The desert tortoise also has high potential to occur in the desert dry wash woodland on the site and one area of Sonoran creosote bush scrub immediately south of the woodland. The woodland habitat continues, undisturbed, to the northwest where it is contiguous to other undisturbed habitat areas that ultimately adjoin designated critical habitat and other areas where the desert tortoise occurrences have been documented.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

Construction. For this analysis, staff assumes that the entire North of Desert Center Alternative site and all of the vegetation communities on it (i.e., fallow agriculture, Sonoran creosote bush scrub, desert saltbush scrub, desert dry wash woodland, active agriculture, developed) as well as some potential jurisdictional waters of the State (e.g., desert dry wash woodland and disturbed wetland) would be permanently lost as a result of vegetation clearing, grading, and construction of the solar facilities, potentially affecting special-status plant species, particularly Coachella Valley milk-vetch and Emory's crucifixion thorn. However, staff also assumes that some of the potential jurisdictional areas, in particular the large wash dividing the northern portion of the site from the southern portion of the site, would be avoided when siting the facility.

Few impacts to special-status animal species would be expected because the North of Desert Center Alternative site is largely fallow agricultural land. However, the habitat is suitable for burrowing owls, which commonly use agricultural land for foraging during winter or breeding seasons. Burrowing owl biology, threats, and conservation status are described above (Section C.2.5.1, **Special-Status Species**). Although the CNDDDB does not report burrowing owls within 5 miles of the site, they have been observed breeding on the proposed Palen Solar Power Project site approximately 5.5 miles northwest of the North of Desert Center Alternative site (BLM and CEC 2010b). Burrowing owls may occur on the North of Desert Center Alternative site and, if present,

nest sites or foraging habitat could be impacted by development of a solar project on the site.

Multiple observations of the desert tortoise have been reported to the CNDDDB within 5 miles of the North of Desert Center Alternative site, including records adjacent to or within the northern and eastern portion of the site. As described above, the desert tortoise has high potential to occur in desert dry wash woodland and Sonoran creosote bush scrub on the North of Desert Center Alternative site. Since these areas would be impacted by the alternative project, there is high potential for impacts to desert tortoise.

There is some potential for other special-status species, including Harwood's milk-vetch, northern harrier, loggerhead shrike, American badger, and desert kit fox to be impacted on the North of Desert Center Alternative site because potential habitat for these species is present and would be impacted by development of the alternative.

Because the primary wash on site would be avoided by project design, as recommended in staff's **Condition of Certification BIO-22**, impacts to wildlife movement across the site in desert dry wash woodland connecting undeveloped or undisturbed lands on either side of the site could be minimized. However, this east-west connectivity would likely be disrupted to some extent due to the construction and other disturbances on either side of the wash.

Additional impacts to vegetation communities, and possibly special-status species, would occur due to the construction of linear facilities (e.g., transmission lines) associated with a solar project on the North of Desert Center Alternative site.

General Construction Impacts to Wildlife. Likely construction impacts to wildlife residing on the North of Desert Center Alternative site would be as discussed above (Section C.2.5.2, **Impacts during Construction**). These impacts would include disturbance, displacement, injury, or mortality during project construction. Burrowing and ground-dwelling animals in the project area could become entrapped in construction trenches, be crushed by construction vehicles or equipment, or be harmed by project personnel. In addition, construction may attract predators or crush animal burrows or nests, potentially causing entombment and mortality.

Migratory and Resident Birds; Special-status Bird Species Impacts. The North of Desert Center Alternative site provides foraging, cover, or breeding habitat for numerous migratory and resident bird species, including special-status species. Absent mitigation, project construction could destroy nesting birds, in violation of the Migratory Bird Treaty Act.

Spread of Nonnative and Invasive Weeds. Construction of a solar project at the North of Desert Center Alternative site could cause the introduction or dispersal of invasive or exotic weeds. The permanent and temporary earth disturbance adjacent to native habitats would increase the potential for exotic, invasive plant species to establish and disperse into native plant communities, which leads to community and habitat degradation.

Excessive Noise. Noise from construction activities on the North of Desert Center Alternative site could temporarily discourage wildlife from foraging and nesting

immediately adjacent to the project area. Many bird species rely on vocalization during the breeding season to attract a mate within their territory. Noise levels from certain construction activities could reduce the reproductive success of nesting birds.

Operational Impacts. Operation of the project at the alternative site would cause impacts to wildlife similar to those described above (Section C.2.5.2, **Impacts during Operation**). These would include increased avian mortality due to collision with new transmission lines, mirrors, and central tower. Other operational impacts would include potential incineration if birds fly through heliostat “standby points.”

An increased incidence of accidental wildfire is also a possibility during operation (although the potential is low) from downed transmission lines. Additionally, there would be the potential for edge effects to special-status animal species in surrounding habitat areas from operational night lighting or noise. Desert tortoises in the area could be subjected to increased predation by common ravens or other animals. Ravens were observed during reconnaissance surveys on the site, and may increase in numbers due to an increase in perching and nesting sites and potentially increased food and/or water sources provided by project facilities. Desert tortoise could also be injured or killed by vehicles on project access roads.

Comparison to Proposed Project. Definitive conclusions about the magnitude of potential adverse impacts to biological resources cannot be made in the absence of site-specific survey and project design information for the North of Desert Center Alternative site. However, development of a solar project at the North of Desert Center Alternative site would impact fewer biological resources compared to the proposed project site because the site is primarily fallow agricultural land, whereas development at the proposed project site would occur primarily on land supporting native vegetation and habitat. Staff’s proposed conditions of certification would mitigate for the Reduced Acreage Alternative’s direct, indirect, and cumulative impacts to biological resources. These conditions are identical to those for the proposed project.

SR-62/RICE VALLEY ROAD TRANSMISSION LINE ALTERNATIVE

The SR 62/Rice Valley Road Transmission Line Alternative would interconnect to Western’s 161-kV/230-kV Parker-Blythe transmission line at the same location as the proposed project transmission line. This alternative transmission line would exit the power block directly to the east and follow a proposed access road within the heliostat field. The tie-in would then turn north inside the RSEP property boundary and run along the RSEP’s circular perimeter road to the north and northwest. At the north end of the heliostat field, the route would traverse the construction laydown area on previously disturbed land over a distance of approximately 500 feet to the southern side of State Route 62. The route would follow State Route 62 approximately 3.8 miles east to the junction of Rice Valley Road. It would then trend south to follow the unpaved Rice Valley Road for 4.1 miles to its juncture with the applicant’s proposed new transmission line alignment and continue southeast for 5.4 miles along the proposed alignment to Western’s Parker-Blythe transmission line. The SR 62/Rice Valley Road Transmission Line Alternative route is illustrated in **Alternatives Figure 4**.

The SR-62/Rice Valley Road Transmission Line Alternative is evaluated in this SA/DEIS because it would:

1. Avoid the permanent loss of 13.4 acres of foraging and cover habitat for plant and animal species, including the state and federally listed threatened desert tortoise.
2. Avoid the creation of a new 4.6-mile vehicle access route between the proposed solar facility and the proposed junction of the new transmission line access road with the existing Rice Valley Road. The proposed new vehicle access route would necessitate additional enforcement and maintenance to prevent unauthorized off-road vehicle access, propagation of new, unauthorized vehicle routes, and consequent habitat damage, soil erosion, and vehicle disturbance.

SETTING AND EXISTING CONDITIONS

The SR-62/Rice Valley Road Transmission Line Alternative alignment would be in the same general area as the proposed project, and the setting for this Alternative is the same as for the proposed project except that the generator tie-line would follow a different route to avoid the need for a new 4.6-mile access road and transmission corridor across undeveloped habitats. All other project elements, including the solar field and interconnection substation would be the same as described for the proposed project in Section C.2.5 above. Although biological field surveys of the alternative alignment have not been carried out between the heliostat field and the point at which the proposed project corridor connects to Rice Valley Road, this area is within the general region described for the proposed project. Similar habitats and species are expected to occur along the alternative alignment, with the main difference being that the alternative alignment occurs adjacent to SR-62 and Rice Valley Road, and the line would be sited in areas more disturbed by human activity than those described for the proposed project. Please see the discussion of existing conditions under Section C.2.5.1.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

The SR-62/Rice Valley Road Transmission Line Alternative would result in reduced habitat disturbance as compared with the proposed project because it would be sited along existing roadways along its entire length, eliminating the need for the construction of a new access road. Additionally, the alternative route would be in more disturbed areas along existing roads and adjacent to existing power lines along portions of the route, as compared with the proposed project generator tie-line alignment. The areas disturbed by the SR-62/Rice Valley Road Transmission Line Alternative would be of lower quality for wildlife than those disturbed by the proposed project. It should be noted that the alternative route is longer than the proposed route, and would require 30 to 35 additional tower bases, compared with the proposed route, with additional construction disturbance at each additional tower location. All of the additional disturbance would be in areas nearer to existing human influence (e.g., roadways) than the western segment of the proposed project alignment.

Biological field surveys have not been conducted on the alternative route along SR-62 and Rice Valley Road north of the proposed project junction, although similar habitats and species are expected to occur. It is likely that similar special-status species would occur along this route, such as special-status plants, desert tortoise, and burrowing owl.

Due to the alignment's proximity to a major highway, established road, and an existing power line corridor, staff anticipates that impacts to biological resources would be reduced. Therefore, even if special-status species are found along the alternative route, the habitat impacted by this Alternative is likely to be of lower quality for these species than the proposed route. Therefore, impacts to general and special-status species would be of the same types as described for the proposed project (see Section C.2.5.2), but would be slightly lower in magnitude.

The SR 62/Rice Valley Road Transmission Line Alternative would increase the total length of the transmission line by approximately 4.4 miles (CH2MHill 2010d). This increase in length would slightly increase the potential for birds to collide with or be electrocuted by the transmission line. Because the new route would be located less than 0.25 mile from the Colorado River Aqueduct in some places, while the proposed route is over two miles from the aqueduct at the nearest location, any birds drawn to the aqueduct as a water source could be at an increased risk for collision with the transmission lines. However, staff's proposed Condition of Certification **BIO-8** (Impact Avoidance and Minimization Measures) would require the transmission line and all electrical components to be designed, installed, and maintained in accordance with the Avian Power Line Interaction Committee's (APLIC's) *Suggested Practices for Avian Protection on Power Lines* (APLIC 2006) and *Mitigating Bird Collisions with Power Lines* (APLIC 1994) to reduce the likelihood of bird electrocutions and collisions. Therefore, impacts to birds from collisions and electrocutions would be less than significant under CEQA with implementation of staff's proposed Condition of Certification **BIO-8**.

Staff's proposed conditions of certification would mitigate for the SR 62/Rice Valley Road Transmission Line Alternative's direct, indirect, and cumulative impacts to biological resources. These conditions are identical to those for the proposed project, except that the compensatory mitigation acreages recommended for desert tortoise habitat (staff's proposed Condition of Certification **BIO-16**) and State waters (staff's proposed Condition of Certification **BIO-22**) are revised to reflect the slightly reduced acreage of permanent impacts.

NO PROJECT/NO ACTION ALTERNATIVE

No Project and No Action on Rice Solar Energy Project transmission line application and interconnection request. No CDCA land use plan amendment.

Under this alternative, the proposed Rice Solar Energy Project would not be approved by the Energy Commission; BLM would not approve the transmission line application and would not amend the CDCA Plan; and Western would not approve the interconnection request. As a result, no solar energy project would be constructed on the project site, BLM would continue to manage the land encompassing the transmission line consistent with the existing land use designation in the CDCA Land Use Plan of 1980, as amended, and Western would continue to operate the Parker Blythe Transmission Line under current conditions.

Because there would be no amendment to the CDCA Plan and no solar project approved for the site under this alternative, it is expected that the site would continue to

remain in its existing condition, with no new structures or facilities constructed or operated on the site. As a result, none of the impacts to biological resources from the proposed project would occur and none of the benefits of the proposed project would occur. In the absence of this project, other renewable energy projects may be constructed to meet State and Federal mandates, and those projects would have similar impacts in other locations.

CUMULATIVE IMPACTS

GEOGRAPHIC EXTENT

The “geographic extent” of the cumulative analysis of impacts to biological resources refers to the area within which cumulative impacts are likely to occur. For the RSEP, the geographic extent varies depending on the resource being evaluated. For example, the geographic extent for impacts to a special-status species generally includes that species’ entire range, including the California desert and beyond. However, for a special-status species that occurs in a series of isolated populations, cumulative effects analysis may appropriately focus on relatively small, local populations as well as their wider geographic distribution. This situation often applies to plants or animals with specialized habitat requirements such as mountain ranges or windblown sand. For species whose geographic range extends outside California, cumulative effects for CEQA purposes may appropriately focus on cumulative impacts within California, while the analysis for NEPA purposes may extend to other states. The following subsections describe the geographic extent under consideration for cumulative impacts to each biological resource that would be affected by the proposed project.

Vegetation Communities

The geographic extent of the analysis of cumulative impacts to vegetation communities includes the entire NECO planning area (see **Biological Resources Figure 6**). The NECO planning area is located in the southeastern California Desert Conservation Area (CDCA). It occurs primarily in the Sonoran Desert region but includes a smaller portion of the southern Mojave Desert region. The NECO planning area comprises 5,547,665 acres of private, federal, and State land. The majority of the planning area land (3,823,194 acres, or 69 percent) is public land managed by BLM (BLM and CDFG 2002).

The entire RSEP project area is mapped as Sonoran creosote bush scrub in the NECO plant communities dataset that is based on the 1996 California Gap Analysis Project prepared by the Biogeography Lab at the University of California, Santa Barbara and coordinated through the USGS Biological Resources Division. A total of 3,829,999 acres of Sonoran creosote bush scrub is mapped within the NECO planning area.

Threats to vegetation communities in the NECO planning area include habitat loss and fragmentation due to development, fire, off-highway vehicle activity, cattle and sheep grazing, overdrawn groundwater, and the spread of invasive plant species (BLM and CDFG 2002). Current and foreseeable renewable energy developments in the planning area contribute cumulatively to impacts to vegetation communities through loss and fragmentation of habitat, contribution to groundwater depletion, and contribution to the

spread of nonnative and invasive weeds. Cumulatively, impacts of these projects to vegetation communities in the NECO planning area would be significant.

Special-Status Plants

The geographic extent of the analysis of cumulative impacts to special-status plants includes the entire NECO planning area. A variety of special-status plant species have ranges that extend through the Mojave and Colorado Deserts of the NECO planning area, and several are endemic to the planning area. Two special-status plants occur on the RSEP and generator tie-line site: chaparral sand-verbena (CNPS List 1B.1 and BLM Sensitive) and Harwood's milk-vetch (CNPS List 2.2). Threats to special-status plants in the California deserts include habitat loss and fragmentation due to development, off-highway vehicle activity, cattle and sheep grazing, overdrawn groundwater, and the spread of invasive plant species (CDFG, 2005). Current and foreseeable renewable energy developments in the Mojave Desert contribute to impacts to special-status plants through loss and fragmentation of habitat to development, contributing to depletion of groundwater supplies, and contributing to the spread of nonnative and invasive weeds. Cumulatively, impacts of these projects to special-status plants in the NECO planning area would be significant.

Common Wildlife

The geographic extent of the analysis of cumulative impacts to common wildlife includes the entire California desert. Common wildlife, including large and small mammals, bats, most migratory and resident birds, reptiles, amphibians, and invertebrates, occur at generally low density in the California desert due to the limited resources present in this arid environment. Naive migratory and resident birds of the California desert are protected under the federal Migratory Bird Treaty Act and California Fish and Game Code Section 3513. Most common wildlife species that occur within the NECO planning area range throughout the California deserts and often beyond. However, even common species are subject to threats such as ongoing habitat loss due to urbanization, agriculture, and energy and infrastructure developments; habitat fragmentation and consequent disruption of regional and local movement corridors; grazing; off-highway vehicle use; groundwater depletion; reduced prey availability; pesticide use; and (for birds) electrocution on power lines. Current and foreseeable renewable energy developments in the California deserts contribute to the loss and damage of habitat through reduced habitat availability; habitat fragmentation; reduced prey base; increased noise and disturbance; and other disruption of natural areas. Cumulatively, impacts of these projects to common wildlife in the California deserts would be significant.

Desert Tortoise

The geographic extent of this analysis of cumulative impacts to desert tortoise is the range of the Mojave desert tortoise population, as recognized by the USFWS (USFWS 1994b), which includes the RSEP project area. The Mojave population's range encompasses the area north and west of the Colorado River in the Mojave and Sonoran/Colorado deserts in California, southern Nevada, southwestern Utah, and extreme northwestern Arizona (USFWS 1994b). This population occurs throughout much of the region, generally in valleys, flat areas, fans, bajadas, and washes below 4,000 feet in native desert vegetation (e.g., creosote bush, saltbush scrub, Joshua tree,

Mohave yucca, and ocotillo-creosote vegetation communities), but also in steeper areas and higher elevations, in lower numbers. Desert tortoise biology and reasons for listing it as threatened are described above (Section C.2.5.1, **Special-Status Species**).

To promote substantial populations for desert tortoise recovery in the Mojave population's range, the 1994 Recovery Plan (USFWS) designated six Recovery Units traversing all four abovementioned states. The establishment of the Recovery Units is intended to protect the species and its habitat requirements so that populations will naturally increase to levels acceptable for delisting (i.e. 50,000 breeding adults per recovery unit). However, desert tortoises are slow-growing animals that do not reach sexual maturity until age 15 to 20 years and have a low reproductive rate over a long period of reproductive potential; these life history characteristics hinder recovery since tortoises experience high mortality rates prior to reaching sexual maturity (USFWS 2008a).

Renewable projects operating and proposed in the range of the Mojave desert tortoise population further contribute to the ongoing loss and fragmentation of its habitat. These projects may also increase the abundance of ravens, increasing predation pressure on desert tortoises. Cumulatively, the impacts of these projects to desert tortoises in the Mojave population would be significant.

Mojave Fringe-Toed Lizard

The geographic extent of the analysis of cumulative impacts to Mojave fringe-toed lizard includes the animal's entire geographic range, the deserts of Los Angeles, Riverside, and San Bernardino Counties in California and La Paz County in Arizona. In the NECO planning area, Mojave fringe-toed lizard is known from aeolian sand habitats around Bristol Dry Lake, Cadiz Dry Lake, Dale Dry Lake, Rice Valley, Pinto Basin, Palen Dry Lake, and Ford Dry Lake (BLM and CDFG 2002). It is listed as a California Species of Special Concern by CDFG and is a BLM Sensitive Species. Biology and threats are described above (Section C.2.5.1, **Special-Status Species**). Current and foreseeable renewable energy developments in the range of the Mojave fringe-toed lizard contribute to the loss and damage of habitat through development, fragmentation, and disruption of aeolian sand movement. Cumulatively, impacts of these projects to the Mojave fringe-toed lizard throughout its geographic range would be significant.

Golden Eagle

The geographic extent of this analysis of cumulative impacts to the golden eagle includes its breeding and breeding-season foraging habitat throughout the California desert. Golden eagle biology, threats to the species, and its conservation status are described above (Section C.2.5.1, **Special-Status Species**). In terms of breeding habitat and breeding season biology, the most important cumulative impacts to golden eagles are the potential for loss or disruption of nesting sites, and the loss of productive foraging habitat surrounding nest sites. Breeding golden eagles forage widely but are limited in their foraging ranges by the necessity of returning to nest sites to tend eggs and feed young. Outside the breeding season, golden eagles are less limited in available foraging ranges, and cumulative loss of foraging habitat is less likely to affect regional population viability. Current and foreseeable renewable energy developments in the California deserts contribute to the loss and degradation of breeding-season

foraging habitat through land use changes, a reduction in prey base, and the disruption of natural areas. Due to the locations of renewable energy projects on the desert valleys and bajadas, rather than remote mountains, cumulative impacts to known or potential nesting sites are relatively minor. However, cumulative impacts of these projects to golden eagle breeding-season foraging habitat surrounding known and potential nesting areas in the California deserts would be significant.

Prairie Falcon

The geographic extent of this analysis of cumulative impacts to the prairie falcon includes its breeding and breeding-season foraging habitat throughout the California desert. Prairie falcon biology, threats to the species, and its conservation status are described above (Section C.2.5.1, **Special-Status Species**). Its breeding habitat and breeding season foraging patterns and limitations are similar to those described above for golden eagle. Like the golden eagle, it nests in cliffs and forages over a broad variety of vegetation types. In the desert, it appears to favor sparse shrubland for foraging (BLM and CDFG 2002). Current and foreseeable renewable energy developments in the California deserts contribute to the loss and damage of habitat through land use changes, a reduction in prey base, and the disruption of natural areas. Due to the locations of renewable energy projects on the desert valleys and bajadas, rather than remote mountains, cumulative impacts to known or potential nesting sites are relatively minor. However, cumulative impacts of these projects to prairie falcon breeding-season foraging habitat surrounding known and potential nesting areas in the California deserts would be significant.

Burrowing Owl

The geographic extent of this analysis of cumulative impacts to the western burrowing owl includes its distribution throughout the California desert. Burrowing owl biology, threats to the species, and its conservation status are described above (Section C.2.5.1, **Special-Status Species**). Current and foreseeable renewable energy developments in the California deserts contribute to the loss and damage of habitat through land use changes, reduction in prey base and the disruption of natural areas. Cumulatively, impacts of these projects to burrowing owl populations in the California deserts would be significant.

Special-Status Passerine Birds

The geographic extent of this analysis of cumulative impacts to special-status passerine bird populations includes their distributions throughout the California desert. Several special-status passerine bird species occur throughout the California desert and surrounding areas. Loggerhead shrike was documented on the project site. This and other special-status shrubland species, including Le Conte's thrasher and Crissal thrasher, may nest onsite. Native resident birds are protected under the federal Migratory Bird Treaty Act and California Fish and Game Code Section 3513. Biology, threats, and conservation status of these birds are described above (Section C.2.5.1, **Special-Status Species**). Current and foreseeable renewable energy developments in the California desert contribute cumulatively to the loss and degradation of their habitat through land use changes, a reduction in prey base, and the disruption of natural areas. Cumulatively, impacts to special-status passerine bird populations in the California desert area would be significant.

Large Mammals (Nelson's Bighorn Sheep, Burro Deer, and Yuma Mountain Lion)

The geographic extent of this analysis of cumulative impacts to large mammals includes their distributions throughout the California desert. The biology, threats, and conservation status of Nelson's bighorn sheep, burro deer, and Yuma mountain lion are described above (Section C.2.5.1, **Special-Status Species**). All three of these animals require regular access during summer to drinking water and shaded cover during summer. These are generally found in canyons and riparian corridors of the scattered desert mountain ranges. Thus, all three species are found in scattered, partially isolated small habitat areas. Nelson's bighorn sheep and burro deer must periodically move among isolated habitat areas to sustain regional population segments. Yuma mountain lions may need to move more frequently among habitat patches to capture enough prey for survival. Due to the locations of renewable energy projects on the desert valleys and bajadas, rather than remote mountains, cumulative impacts to primary habitat areas are relatively minor. Instead, the most important cumulative impact to these animals is the reduced opportunity for movement among mountain ranges. Cumulative impacts of these projects to large mammal movement among habitat areas in the California deserts would be significant.

American Badger and Desert Kit Fox

The geographic extent of this analysis of cumulative impacts to American badger and desert kit fox populations includes their distributions throughout the California desert. The biology, threats, and conservation status of both animals are described above (Section C.2.5.1, **Special-Status Species**). Current and foreseeable renewable energy developments in the California desert contribute cumulatively to the loss and degradation of habitat through land use changes, fragmentation, and the disruption of natural areas. Cumulatively, impacts of these projects to American badger and desert kit fox populations in the California desert would be significant.

Special-status Bats

The geographic extent of this analysis of cumulative impacts to special-status bat populations includes their distributions throughout the California desert. The biology, threats, and conservation status of special-status bats are described above (Section C.2.5.1, **Special-Status Species**). Current and foreseeable renewable energy developments in the California desert contribute cumulatively to the loss and damage of habitat through land use changes, reduction in prey base, and the disruption of natural areas. Cumulatively, impacts of these projects to special-status bat populations in the California desert area would be significant.

Wildlife Movement and Connectivity

The geographic extent of this analysis of cumulative impacts to wildlife movement is the Rice Valley and surrounding mountain ranges at a local scale and, more broadly, the entire California desert. Threats to wildlife movement throughout the desert include large-scale land use changes, such as agriculture, infrastructure, commercial and residential development, and military uses. Wildlife movement in the Rice Valley contributes more broadly to movement throughout the entire California desert. Current and foreseeable renewable energy developments in the California desert contribute to

the loss and damage of wildlife movement corridors. Cumulatively, impacts to corridors in the California desert would be significant.

Jurisdictional Waters of the State

The geographic extent of this analysis of cumulative impacts to jurisdictional waters of the State is the NECO planning area. A variety of playas, seeps, lakes, and drainages are found throughout the planning area. Some of these range over large acreages. Most of the jurisdictional desert washes and channels in the planning area flow ephemerally in response to heavy rain storms. Desert wash habitats, which make up the majority of jurisdictional waters in the planning area, provide habitat for a variety of species and play an important role in conveying surface flows during storm events. Threats to jurisdictional waters include large-scale land use conversion, including agriculture, infrastructure, and commercial and residential development, as well as off-road vehicle use, pesticide use, and mining. Current and foreseeable renewable energy developments in the NECO planning area contribute to the loss and alteration/damage of jurisdictional waters. Cumulatively, impacts of these projects to jurisdictional waters in the NECO planning area are significant.

EXISTING CUMULATIVE CONDITIONS

Over the past two hundred years, California's deserts have been subject to major human-induced changes that have threatened native plant and animal communities by habitat loss, fragmentation, and degradation. Some of the most conspicuous threats are those activities that have resulted in large-scale habitat loss due to urbanization, agricultural uses, landfills, military operations, mining, as well as activities that fragment and degrade habitats such as roads, off-highway vehicles, recreational use, and grazing (Berry et al. 1996; Boarman and Sasaki 2006; Avery 1997; Jennings 1997). In addition, these development pressures have facilitated the introduction of non-native plant species and increases in predators such as ravens, which contribute to population declines and range contractions for many special-status plant and animal species (Boarman 2002).

Development is limited in the general area around the RSEP site. **CUMULATIVE IMPACTS Table 2** identifies ten existing projects in the Rice Valley area and surrounding area within approximately 20 miles of the RSEP site. The projects closest to the RSEP site include the Rice Valley Grazing Allotment, the Arizona-California Railroad, and the Colorado River Aqueduct. In addition, SR-62 runs in an east-west direction immediately north of the RSEP site, in parallel with the adjacent aqueduct and railroad. Other existing projects in the Rice Valley area include various transmission lines, the Iron Mountain Pumping Plant and airport, and recreational opportunities. More distant projects (greater than 20 miles from the RSEP) in eastern Riverside County include Interstate 10 to the south, the Eagle Mountain Pumping Plant, the Blythe Energy Project, the Kaiser Mine (now inactive), and the Devers-Palo Verde Transmission Line.

In consideration of the existing cumulative conditions encompassing the Rice Valley area and surrounding area, the RSEP would contribute to the loss of habitat for sensitive species including desert tortoise, burrowing owl, and other species described above. The combined effects of existing development and the proposed project's additional incremental effect on biological resources would be cumulatively significant.

Habitat loss and fragmentation has already contributed to the decline of several California desert associated species. The proposed project's contribution to these effects would be mitigated through staff's recommended **Conditions of Certification BIO-1** through **BIO-26**. With implementation of these Conditions of Certification, the project's contribution to cumulative effects would not be considerable. Cumulative impacts to specific resources and individual species are discussed in greater detail below.

Vegetation Communities

As described above under **Geographic Extent**, the entire RSEP project area is mapped as Sonoran creosote bush scrub in the NECO plant communities dataset. A total of 3,829,999 acres of Sonoran creosote bush scrub is mapped within the entire NECO planning area. The RSEP would have permanent and long-term impacts to approximately 1,770 acres of desert vegetation, primarily creosote bush scrub. Regional and project-level mapping data are not available to allow calculation of acreages or percentages of impacts to other vegetation types at finer scale. This acreage is approximately 0.04 percent of the Sonoran creosote bush scrub in the NECO planning area. The RSEP would contribute incrementally to the cumulatively significant impacts of existing and future projects to Sonoran creosote bush scrub habitat. Sonoran creosote bush scrub is a common and widespread community in the southeastern deserts of California. Large, intact blocks of habitat such as that in the Rice Valley are important to wildlife movement and to foraging and breeding habitat for wildlife, including special-status species and State and federally listed species. The RSEP's contribution to regional cumulative impacts to these habitat values are addressed below, under special-status species and wildlife movement.

Staff's proposed Conditions of Certification **BIO-1** through **BIO-11**, and **BIO-16** would minimize the proposed project's contribution to cumulative loss of Sonoran creosote bush scrub. While acquisition does not prevent the net loss of habitat that would result from the RSEP, it is expected to minimize future loss of protected habitat by placing a permanent conservation easement and deed restrictions on private lands that could otherwise be converted for urban, agricultural, or energy development. Given the relatively small proportion of Sonoran creosote bush scrub habitat to be lost for this project and the incorporation of mitigation measures described above, the RSEP's contribution to the loss of Sonoran creosote bush scrub in the region is not cumulatively considerable and would be less than significant with mitigation incorporated.

Special-Status Plants

The RSEP's incremental contribution to cumulative impacts to special-status plants would be minor. Two special-status species would be impacted by the RSEP: chaparral sand-verbena and Harwood's milk-vetch. Chaparral sand-verbena is widespread in the Colorado Desert, and is not rare in this region (see Section C.2.5.1, **Special-Status Species**, above). Impacts to Harwood's milk-vetch and any other special-status plants found on the project site would be avoided or minimized through implementation of staff's proposed Condition of Certification **BIO-12**. The NECO planning area contains an estimated 1,555,915 acres of potential habitat for Harwood's milk-vetch (Based on the BLM NECO Landforms dataset [BLM and CDFG 2002], selecting the following values: undifferentiated dunes; sandy plains; sandy dissected fans; undifferentiated plains;

dissected fans; sand-covered fans). The RSEP would impact approximately 0.1 percent of modeled potential habitat for this species in the NECO planning area. However, the majority of modeled “potential” habitat is not occupied by the plant and this calculation has very limited utility in this analysis. Staff concludes that, due to the relatively low abundance of both plants in the RSEP and generator tie-line footprints, the occurrence of Harwood’s milk-vetch in areas to be avoided due to other resource concerns (sandy washes and similar habitats); the relatively low local conservation concern for chaparral sand verbena, and the mitigation recommended under Condition of Certification **BIO-12**, the RSEP would not make a considerable contribution to the cumulative regional impacts to special-status plants, and its cumulative impact would be less than significant.

Common Wildlife

The RSEP’s incremental contribution to cumulative impacts to common wildlife, including most resident and migratory birds, would be habitat loss and fragmentation. Most common wildlife species range widely over California, and these species have not been identified as conservation priorities because significant population declines and other risk factors have not been identified. The RSEP would contribute incrementally to impacts to common wildlife such as disruption of movement, disturbance, mortality, loss of habitat, and fragmentation. With the incorporation of recommended Conditions of Certification (see **Construction Impacts to Common Wildlife and Habitat** in Section C.2.5.2, above), this incremental contribution would be mitigated to the extent feasible and would not result in the loss of a population or a trend toward federal or State listing for any common wildlife species. With incorporated mitigation, the RSEP would not make a considerable contribution to the cumulative regional impacts to common wildlife, when combined with the effects of past and future projects in the NECO planning area, and its impact would be less than significant.

Desert Tortoise

The RSEP’s incremental contribution to cumulative impacts to desert tortoise would be similar to the impacts of other solar developments in the range of the Mojave population, and would include loss of habitat, interference with regional movement, stress and potentially illness or mortality from translocation, and indirect impacts from an increase in predators such as the common raven. The current USGS Desert Tortoise Habitat Model (Nussear et al. 2009) maps the project area and most of Rice Valley as “Medium Quality” desert tortoise habitat, with scores of 0.3-0.7 on a scale of 0 to 1 (0 being the lowest quality and 1 being the highest quality). The model is a predictive model for mapping the potential distribution of desert tortoise habitat and is useful tool for evaluating different land-use issues that tortoises face at a landscape scale. It is not intended to be used, or viewed, as a substitute for ground-based and site-specific field surveys. Model scores reflect a hypothesized habitat potential given the range of environmental conditions where tortoise occurrence was documented. The report (Nussear et al. 2009) specifically states:

“ . . . there are likely areas of potential habitat for which habitat potential was not predicted to be high, and likewise, areas of low potential for which the model predicted higher potential. Finally, the map of desert tortoise potential habitat that we present does not account either for anthropogenic effects, such as urban

development, habitat destruction, or fragmentation, or for natural disturbances, such as fire, which might have rendered potential habitat into habitat with much lower potential in recent years”.

Based on staff’s field observations and historic land uses, desert tortoise habitat quality on the RSEP site is somewhat degraded. Even so, the site is occupied habitat and the observations of tortoise eggshell fragments indicate successful desert tortoise reproduction. The RSEP would have permanent and long-term impacts to approximately 1,530 acres of habitat at the solar field site, and approximately 119 acres along the generator tie-line corridor. This would amount to less than 0.06 percent of the total medium quality habitat mapped within the NECO planning area in the habitat model (2,797,866 acres).

Staff has proposed mitigation to reduce project-level impacts to desert tortoise, including construction minimization measures (**BIO-8**), clearance surveys and exclusion fencing (**BIO-14**), preparation and implementation of a translocation plan (**BIO-15**), acquisition and conservation of compensation lands (**BIO-16**), and preparation and implementation of a plan to control ravens (**BIO-17**). Together these measures would reduce project-level impacts of the solar generator, generator tie-line, and interconnector substation to less than significant under CEQA and would fully mitigate those impacts under CESA. Staff concludes that, with incorporation of these measures, those components of the RSEP’s contribution to significant cumulative effects to desert tortoises would not be considerable. Staff has not determined potential significance of cumulative impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

Mojave Fringe-Toed Lizard

The RSEP’s impacts to Mojave fringe-toed lizard would largely be limited to construction-related impacts during construction or upgrade work on the generator tie-line alignment and the Parker-Blythe #2 transmission line alignment. Potential habitat on the solar generator site is marginal, patchy, and not extensive. Staff’s recommended Conditions of Certification **BIO-8** would minimize potential adverse impacts to the species and its habitat during transmission line work. Mojave fringe-toed lizard occurs in the Danby Dunes, less than one mile south of the project site. If the RSEP causes an increase in predators such as the common raven due to food and nesting habitat subsidies, then these indirect project impacts could affect the off-site Mojave fringe-toed lizard population. Staff’s proposed Condition of Certification **BIO-17** requires the preparation and implementation of a Raven Management Plan to minimize the potential for increases in raven populations related to implementation of the RSEP; therefore, the incremental contribution of the solar generator, generator tie-line, and interconnector substation to cumulative impacts to the Mojave fringe-toed lizard would be reduced to less than significant with mitigation incorporated. Staff has not determined potential significance of cumulative impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

Golden Eagle

The RSEP would contribute incrementally to the cumulative loss of golden eagle foraging habitat. The RSEP solar generator site does not provide suitable golden eagle

nesting habitat, but there are inactive recent golden eagle nest sites known within 10 miles of the proposed project site (Bloom 2010), and these sites could be used again in the future. The entire RSEP site, including the proposed generator tie-line alignment and the existing Parker-Blythe #2 transmission line alignment, provides potential foraging habitat and is within foraging range of known or potential nest sites. Other renewable developments, both existing and proposed, in the NECO planning area would have similar potential impacts, and cumulatively, development in the California deserts would have significant impacts on golden eagles. Implementation of staff's proposed Conditions of Certification **BIO-1** through **BIO-11** would minimize project impacts to potential golden eagle foraging habitat. Condition of Certification **BIO-16**, which would require compensatory land acquisition to mitigate impacts to desert tortoise (described above), would mitigate project-specific loss of foraging habitat to less-than-significant levels. Condition of Certification **BIO-25** would require compliance with the Bald and Golden Eagle Protection Act as part of the Avian and Bat Protection Plan and a monitoring study to address potential bird injury or mortality, including adaptive management actions. With implementation of these measures, the solar generator, generator tie-line, and interconnector substation's contribution to significant cumulative impacts to golden eagles would be less than considerable. Staff has not determined potential significance of cumulative impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

Prairie Falcon

A prairie falcon was observed flying over the project site during surveys for the RSEP (SR 2009a) and nesting prairie falcons were reported in the surrounding mountains (Bloom 2010). This species has a similar life history as the golden eagle, and impacts would be similar to those described for golden eagle above. Prairie falcons are likely to forage over the RSEP site year-around. However, the prairie falcon's overall distribution appears to be stable (BLM and CDFG 2002), and it has no federal conservation status other than its protection under the Migratory Bird Treaty Act. Staff concludes that the solar generator, generator tie-line, and interconnector substation's incremental contribution to cumulative impacts to prairie falcon would be less than significant. Staff has not determined potential significance of cumulative impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

Burrowing Owl

The RSEP would contribute incrementally to the cumulative loss of burrowing owl wintering habitat. Recently active burrows were identified on site during surveys in 2009 and 2010. However, there were no sightings of the owls themselves during the breeding season surveys and the condition of the burrows suggests that burrowing owls had used the site as wintering habitat, earlier in the year. Although no burrowing owls nested on the site in 2009 or 2010, habitat on-site appears suitable for nesting, at least in some years. Impacts from the RSEP would be similar to other solar developments in the region, and could include loss of breeding or wintering habitat, disturbance due to human activities, and destruction of active (nesting or wintering) burrows. However, due to the low level of use, and an apparent rarity of breeding on-site, the RSEP solar generator, generator tie-line and interconnector substation's incremental contribution to cumulative impacts to burrowing owls would be minor. Implementation of staff's proposed Conditions of Certification **BIO-19** (Burrowing Owl Impact Avoidance,

Minimization, and Compensation Measures) and **BIO-16** (Desert Tortoise Compensatory Mitigation) would reduce the RSEP's contribution to cumulative impacts to a less-than-significant level under CEQA. Staff has not determined potential significance of cumulative impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

Special-Status Passerine Birds

The RSEP would contribute incrementally to the cumulative loss of year-round habitat for several special-status birds. Loggerhead shrike was documented on the site. This and other special-status shrubland species, including Le Conte's thrasher and Crissal thrasher, may nest on-site. The RSEP's primary impacts to resident and migratory birds include habitat loss, disturbance to foraging and breeding, and risk of injury or mortality due to collision with project features or incineration at the solar field site. However, due to the low density of birds observed on-site, and the availability of similar or higher-quality habitat in the greater Rice Valley and beyond, the RSEP's incremental contribution to cumulative impacts to resident and migratory birds would be low. This contribution would be further reduced by the implementation of staff's proposed Conditions of Certification **BIO-1** through **BIO-10**, and **BIO-13** which requires pre-construction nest surveys and impact avoidance measures for nesting birds. Condition of Certification **BIO-25** would require an Avian and Bat Protection Plan and a monitoring study to address potential bird injury or mortality, including adaptive management actions. With implementation of these measures, the solar generator, generator tie-line and interconnector substation's incremental contribution to cumulative impacts to special-status passerine birds would be less than significant with mitigation incorporated. Staff has not determined potential significance of cumulative impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

Large Mammals (Nelson's Bighorn Sheep, Burro Deer, and Yuma Mountain Lion)

The RSEP would contribute incrementally to the cumulative reduction in large mammal movement opportunities among mountain ranges. Large mammal movement from the nearby Turtle Mountains, across the project area, to other mountain ranges in the area is restricted by the aqueduct, railroad, SR-62, and large containment berms just north of these features. Even though the RSEP would permanently fence a 1,410-acre area, it is unlikely to have a substantial impact on any occasional use of the Rice Valley for movement. No future projects are planned adjacent to the RSEP that would significantly impair movement, should it occur in the project area. Therefore, the RSEP's incremental contribution to cumulative impacts to large mammals would be less than significant.

American Badger and Desert Kit Fox

The RSEP would contribute incrementally to the cumulative loss and fragmentation of habitat for desert kit fox and, perhaps, badgers. These impacts are similar to impacts that would result from other past and foreseeable future developments within the California desert. However, due to the low density of kit fox and badgers on site, and the fact that no future projects are planned adjacent to the RSEP that would significantly impair movement, the RSEP's contribution to cumulative impacts to badgers and kit fox would be minor. Staff's proposed Condition of Certification **BIO-20** requires impact avoidance and minimization measures for American badgers and desert kit fox.

Condition of Certification **BIO-16**, which requires compensatory mitigation for desert tortoise habitat, would also offset project-specific impacts to these species. Staff concludes that the RSEP's incremental contribution to cumulative impacts to American badger and desert kit fox would be less than significant.

Bats

There is no suitable roosting habitat in or adjacent to the RSEP solar generator site and generator tie-line alignment, and bats in the area likely roost in nearby mountain ranges. However, bats may forage over the project area, and may even be drawn to the area once the RSEP is operational due to the presence of the evaporation ponds. Due to the lack of roosting habitat in or near the project area, and the widespread availability of similar foraging habitat in the Rice Valley and beyond, the incremental contribution of the RSEP solar generator, generator tie-line, and interconnector substation to cumulative impacts to bats would be less than significant. Potential occurrence of bats, including special status bat species, along the Parker-Blythe #2 transmission line alignment is unknown. Staff has not determined potential significance of cumulative impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

Wildlife Movement and Connectivity

As described above for Nelson's bighorn sheep, burro deer, and Yuma mountain lion, wildlife movement between the Rice Valley and the Turtle Mountains to the north is greatly restricted by the presence of the aqueduct, railroad, highway, and berms located along the southern foothills of the mountains just north of the RSEP solar generator site. In addition to large mammals, this restriction affects all terrestrial species, including desert tortoise. Cumulative impacts of these existing facilities are significant restrictions to wildlife movement through the area. Staff's recommended Condition of Certification **BIO-21** would serve to maximize potential wildlife movement around the proposed solar generator site. Construction and upgrades along new and existing transmission line facilities would have minimal impacts to wildlife movement. Therefore, the RSEP's incremental contribution to cumulative impacts to wildlife movement and connectivity would be less than significant.

Jurisdictional Waters of the State

The RSEP would contribute incrementally to cumulative impacts of State-jurisdictional waters in the NECO Planning Area. The most important existing alterations to State jurisdictional waters in the Rice Valley are the Colorado River Aqueduct and upstream berm system that directs flows to the aqueduct siphon points. The existing railroad and highway also affect jurisdictional waters. Jurisdictional waters in the northern part of the Rice Valley consist of dry desert washes and small, ephemeral drainages that drain from the north to the south over the aqueduct siphons and beneath the railroad line. Most of the jurisdictional waters on the RSEP site are minor ephemeral channels that originate on-site, though the project also would affect larger channels along its eastern and western margins and along the generator tie-line alignment. Further, with few exceptions, jurisdictional waters on the site do not support specialized riparian or desert wash vegetation or other special habitat values. The RSEP solar generator and generator tie-line would impact 82.8 acres of State jurisdictional waters. Additional jurisdictional waters may be impacted along the Parker-Blythe #2 transmission line

alignment. This loss would be offset by the implementation of staff's proposed Conditions of Certification **BIO-22**, which requires that the applicant provide compensatory mitigation at a 1:1 ratio for all impacts to State jurisdictional waters, and also requires a number of impact avoidance and minimization measures, including the elimination of the applicant's proposed stormwater detention basin. The applicant would likely fulfill the large majority of this compensatory mitigation requirement through the conservation and management of jurisdictional drainages on the desert tortoise compensatory mitigation lands (see Condition of Certification **BIO-16**). Due to the relative lack of riparian habitat and the small, ephemeral character of most of these channels, the incremental contribution of the solar generator, generator tie-line, and interconnector substation to cumulative impacts to State jurisdictional waters would be less than significant with mitigation incorporated. Staff has not determined potential significance of cumulative impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

FUTURE FORESEEABLE PROJECTS

Foreseeable Projects in the Project Area

As described in **CUMULATIVE IMPACTS Figure 2** and **CUMULATIVE IMPACTS Table 3**, four projects are proposed or under construction within 20 miles of the RSEP. Three of these four projects are proposed solar power developments which would convert approximately 70,160 acres of desert lands to industrial uses. Twenty-three additional developments are proposed or under construction in eastern Riverside County, more than 20 miles from the RSEP. These projects include several solar developments, commercial and residential developments, reconstruction projects, transmission line and substation projects, a pumped storage project, an auto racetrack, a landfill, and a communication project. The DOE and BLM have identified 24 tracts of land as Solar Energy Study Areas in the BLM and DOE Solar Energy Development Programmatic EIS (PEIS) (*in prep*). These areas have been identified for in-depth study of solar development and may be found appropriate for designation as solar energy zones in the future. Five solar trough and solar power tower projects have been proposed along the I-10 corridor approximately 15 miles east of the California-Arizona border. In addition, pending legislation proposes a 941,000-acre national monument between Joshua Tree National Park and Mojave National Preserve.

In consideration of the existing cumulative conditions in eastern Riverside County, these proposed projects have the potential to further reduce and degrade native plant and animal populations, especially sensitive species such as desert tortoise and burrowing owl. Many of the impacts to biological resources that would result from these projects could be mitigated to less than significant at the project level; however, the incremental contribution of each project could be cumulatively considerable even with mitigation. The effects of the RSEP to biological resources, combined with future foreseeable projects in the area, would be similar to the effects identified for the RSEP's contribution combined with existing projects (see **Existing Cumulative Conditions**, above). As described above, the proposed RSEP would similarly contribute to the cumulative loss and degradation of habitat for desert plants and wildlife within the NECO planning area and the greater California desert. **Biological Resources Figure 6** indicates locations of foreseeable future projects within the NECO Planning Area. With the implementation of

staff's recommended Conditions of Certification, these impacts to biological resources (discussed individually in Section C.2.10.2), would be reduced below a level of significance and , for all the RSEP's contribution to cumulative impacts would be less than significant.

Foreseeable Renewable Projects in the California Desert

As shown on **CUMULATIVE IMPACTS Figures 1 and 2** and **Table 1**, a total of 56 solar energy development projects on 544,203 acres and 61 wind energy development projects on 474,258 acres are proposed on BLM land in the California Desert District. Over 25 additional renewable energy projects are proposed, under environmental review, or approved on State and private lands within the deserts of California. This represents a worst-case scenario for cumulative impacts to biological resources, and not all of these projects would ultimately be developed. However, if even a fraction of the more than one million acres of development proposed on BLM lands alone is implemented, this would represent a significant cumulative impact to biological resources including loss and fragmentation of habitat for common and sensitive plants and animals, interruption of wildlife movement corridors, alteration of watersheds, large-scale spread of invasive and non-native weeds, and permanent loss of sensitive vegetation communities.

It should be noted that legislation has been introduced in the United States Congress to create a National Monument that would link Joshua Tree National Park and the Mojave National Preserve. The Monument would potentially include the former Catellus Lands donated by the Wildlands Conservancy to the BLM. Details of the proposed Monument are not yet known, but according to the Wildlands Conservancy, the Monument would preserve 941,000 acres of BLM lands along with their existing uses (recreation, national scenic highway, wildlife corridors, etc.). The establishment of the Monument would restrict future development and would preserve habitat for sensitive species such as desert tortoise, Mojave fringe-toed lizard, and Nelson's bighorn sheep (Wildlands Conservancy 2009). The Monument has not been approved, and details regarding the boundaries and the management actions that would be implemented are currently unknown. If approved, this Monument would aid in the conservation of many of the same species and resources that would be affected by the RSEP and other developments proposed in the region. However, even with the approval and implementation of the Monument proposal, cumulative impacts to biological resources in the California desert would not be offset due to the magnitude of development proposed (i.e., over one million acres on BLM lands and an unknown additional acreage of State and private lands proposed for renewable energy development in the California Desert).

The effects of the RSEP to biological resources, combined with future foreseeable projects in the California desert, would be similar to for the RSEP's contribution combined with existing projects (**Existing Cumulative Conditions**, above), described above. The proposed RSEP would similarly contribute to the cumulative loss and degradation of habitat for desert plants and wildlife within the California desert. With the implementation of staff's recommended Conditions of Certification, these impacts to biological resources (discussed individually in Section C.2.10.2), would be reduced

below a level of significance and , for all the RSEP's contribution to cumulative impacts would be less than significant.

CONCLUSION: CUMULATIVE IMPACTS ANALYSIS

The impacts of the RSEP on biological resources by itself would be mitigated to less than significant at the project level (see **Assessment of Impacts and Discussion of Mitigation**, above). However, the project would also contribute incrementally to cumulatively significant impacts of numerous past, present, and reasonably foreseeable future projects in the California desert. The important cumulative effects of these projects include extensive habitat loss, impaired biological connectivity among remaining habitat areas (i.e., fragmentation), and the degradation of the function and values of remaining habitat from disturbance, invasive plants, fire, disease, and other factors. These cumulative impacts are likely to remain significant, even with implementation of project-specific mitigation. Therefore, although the development of renewable resources in compliance with federal and State mandates is important and required, this land use conversion would result in significant and unavoidable cumulative impacts. The RSEP's location, low density of special-status resources, previous disturbance over much of the site, and proposed mitigation would reduce its incremental contribution to these significant impacts to less than significant with mitigation incorporated for most resources. With the implementation of staff's recommended Conditions of Certification, these impacts to biological resources (discussed individually in Section C.2.10.2), would be reduced below a level of significance and , for the solar generator, generator tie-line and interconnector substation's contribution to cumulative impacts would be less than significant. Staff has not determined potential significance of cumulative impacts along the Western Parker-Blythe 161-Kv OPGW Transmission Line, pending additional biological data.

COMPLIANCE WITH LORS

The proposed project must comply with State and federal laws, ordinances, regulations, and standards (LORS) that address State and federally listed species, as well as other sensitive species and habitats, and must secure the appropriate permits to satisfy these LORS. The Energy Commission has a one-stop permitting process for all thermal power plants rated 50 MW or more under the Warren-Alquist Act (Pub. Resources Code § 25500). Under the act, the Energy Commission's certificate is "in lieu of" other State, local, and regional permits (*ibid*). The Energy Commission's streamlined permitting process accomplishes a primary objective of the Renewable Energy Action Team, as identified in the Governor's Executive Order S-14-08 — to create a "one-stop" process for permitting renewable energy generation facilities under California law. Accordingly, Energy Commission staff has coordinated joint environmental review with the California Department of Fish and Game and the Colorado River Basin Regional Water Quality Control Board, as well as the U.S. Fish and Wildlife Service. Staff has incorporated all required terms and conditions that might otherwise be included in State permits into the Energy Commission's certification process. The conditions of certification described below satisfy the following State LORS and take the place of terms and conditions that, but for the Commission's exclusive authority, would have been included in the following State permits.

In addition, the applicant has submitted an application to the BLM requesting a ROW to construct the proposed project's generator tie-line. Pursuant to the California Desert Conservation Area (CDCA) Plan (1980, as amended), sites associated with power generation or transmission not identified in the CDCA Plan are considered through the Plan Amendment process. Under federal law, BLM is responsible for processing requests for ROWs to authorize such proposed projects and associated transmission lines and other appurtenant facilities on land it manages. The CDCA Plan, while recognizing the potential compatibility of solar generation facilities on public lands, requires that all sites associated with power generation or transmission not identified in the Plan be considered through the Plan Amendment process. BLM would use the following Planning Criteria during the Plan Amendment process:

- The plan amendment process would be completed in compliance with the Federal Land Policy and Management Act (FLPMA), NEPA, and all other relevant Federal law, Executive orders, and management policies of the BLM;
- The plan amendment process would include an EIS (i.e., this joint SA/DEIS) to comply with NEPA standards;
- Where existing planning decisions are still valid, those decisions may remain unchanged and be incorporated into the new plan amendment;
- The plan amendment would recognize valid existing rights;
- Native American Tribal consultations would be conducted in accordance with policy, and Tribal concerns would be given due consideration. The plan amendment process would include the consideration of any impacts on Indian trust assets (please see the **Cultural Resources** section);
- Consultation with the State Office of Historic Preservation (SHPO) would be conducted throughout the plan amendment process (please see the **Cultural Resources** section); and
- Consultation with the US Fish and Wildlife Service (USFWS) would be conducted throughout the plan amendment process.

If the ROW and proposed land use plan amendment are approved by BLM, the proposed transmission facility on public lands would be authorized in accordance with Title V of the FLPMA of 1976 and the Federal Regulations at 43 CFR part 2800. This Environmental Impact Statement (EIS) acts as the mechanism for meeting NEPA requirements, and also provides the analysis required to support a Plan Amendment identifying the facility within the Plan.

Biological Resources Table 9 provides a summary of the proposed project's compliance with federal, State, and local LORS and proposed conditions of certification.

Biological Resources Table 9
Summary of Solar Generator, Generator Tie-Line, and Interconnector Substation
Compliance with LORS¹

Applicable LORS	Description	Rationale for Compliance
FEDERAL		
Federal Endangered Species Act (Title 16, United States Code, section 1531 et seq., and Title 50, Code of Federal Regulations, part 17.1 et seq.)	Designates and provides for protection of threatened and endangered plant and animal species and their critical habitat. "Take" of a federally-listed species is prohibited without an incidental take permit, which may be obtained through Section 7 consultation (between federal agencies) or a Section 10 Habitat Conservation Plan.	Western is consulting with USFWS per Section 7 of the ESA reg. project impacts to desert tortoise (federally listed as threatened); a Biological Opinion is pending. Proposed Conditions of Certification BIO-1 through BIO-10 and BIO-14 through BIO-17 require measures to avoid or mitigate impacts to desert tortoise, including translocation off-site and protection of compensation habitat. These measures would ensure that the project is not likely to jeopardize the continued existence of desert tortoise.
Migratory Bird Treaty (Title 16, United States Code, sections 703 through 711)	Makes it unlawful to take or possess any migratory nongame bird (or any part of such migratory nongame bird) as designated in the Migratory Bird Treaty Act unless permitted by regulation (e.g., duck hunting).	Condition of Certification BIO-13 includes preconstruction nest surveys, no-disturbance buffers around active nests, and monitoring to minimize impacts to nesting migratory birds; Condition of Certification BIO-25 requires preparation and implementation of an Avian Protection Plan and a monitoring study to address potential bird injury or mortality, including adaptive management actions.
Clean Water Act (Title 33, United States Code, sections 1251 through 1376, and Code of Federal Regulations, part 30, section 330.5(a)(26))	Requires the permitting and monitoring of all discharges to surface water bodies. Section 404 requires a permit from the U.S. Army Corps of Engineers (USACE) for a discharge from dredged or fill materials into waters of the US, including wetlands. Section 401 requires a permit from a regional water quality control board (RWQCB) for the discharge of pollutants.	USACE has determined that no jurisdictional Waters of the US are within the solar generator site or generator tie-line alignment.
Bald and Golden Eagle Protection Act (Title 16, United States Code section 668)	Provides for the protection of the bald eagle and the golden eagle by prohibiting, except under certain specified conditions, the take, possession, and commerce of such birds. Defines the "take" of an eagle to include a broad range of actions, including disturbance (i.e., to agitate or bother an eagle to a degree that causes, or is likely to cause, injury, decreased productivity by substantially interfering with behavior, or nest abandonment).	Condition of Certification BIO-16 requires protection of compensation habitat for desert tortoise, that also would serve as golden eagle foraging habitat; Condition of Certification BIO-18 requires preconstruction nest surveys and measures to prevent disturbance to nesting golden eagles; Condition of Certification BIO-25 requires documentation of compliance with the Bald and Golden Eagle Protection Act as part of the Avian Protection Plan and a monitoring study to address potential bird injury or mortality, including adaptive management actions.

Applicable LORS	Description	Rationale for Compliance
California Desert Conservation Area Plan 1980, as amended (reprinted in 1999)	Administered by the BLM; requires that proposed projects are compatible with policies that provide for the protection, enhancement, and sustainability of fish and wildlife species, wildlife corridors, riparian and wetland habitats, and native vegetation resources.	Staff's proposed Conditions of Certification BIO-1 through BIO-26 minimize, avoid, and compensate for impacts to various biological resources covered by the CDCA Plan.
California Desert Protection Act of 1994	An Act of Congress which established 69 wilderness areas, the Mojave National Preserve, expanded Joshua Tree and Death Valley National Monuments and redefined them as National Parks.	Staff's proposed Conditions of Certification BIO-1 through BIO-26 minimize, avoid, and compensate for impacts to various biological resources covered by the California Desert Protection Act of 1994.
Northern and Eastern Colorado Desert Coordinated Management Plan (NECO)	BLM land use plan amendment that resolves issues of resource demands, use conflicts, and environmental quality in the 5.5-million acres planning area located primarily within the Sonoran Desert in southeastern California; provides reserve management for the desert tortoise, integrated ecosystem management for special status species and natural communities for all federal lands, and regional standards and guidelines for public lands (BLM and CDFG 2002).	Staff's proposed Conditions of Certification BIO-1 through BIO-26 minimize, avoid, and compensate for impacts to various biological resources covered by the NECO.
STATE		
California Endangered Species Act of 1984 (Fish and Game Code, sections 2050 through 2098)	Protects California's rare, threatened, and endangered species. "Take" of a State-listed species is prohibited without an Incidental Take Permit.	Conditions of Certification BIO-1 through BIO-10 and BIO-14 through BIO-17 would fully mitigate project impacts to desert tortoise.
California Code of Regulations (Title 14, sections 670.2 and 670.5)	Lists the plants and animals of California that are declared rare, threatened, or endangered.	Conditions of Certification BIO-1 through BIO-10 and BIO-14 through BIO-17 would fully mitigate project impacts to desert tortoise.
Fully Protected Species (Fish and Game Code, sections 3511, 4700, 5050, and 5515)	Designates certain species as fully protected and prohibits the take of such species or their habitat unless for scientific purposes (see also California Code of Regulations, Title 14, section 670.7).	Golden eagle is designated as fully protected. Condition of Certification BIO-16 requires protection of compensation habitat for desert tortoise, that also would serve as golden eagle foraging habitat; Condition of Certification BIO-18 requires preconstruction nest surveys and measures to prevent disturbance to nesting golden eagles; Condition of Certification BIO-25 requires documentation of compliance with the Bald and Golden Eagle Protection Act as part of the Avian Protection Plan and a monitoring study to address potential bird injury or mortality, including adaptive management actions.

Applicable LORS	Description	Rationale for Compliance
Nest or Eggs (Fish and Game Code section 3503)	Protects California's birds by making it unlawful to take, possess, or needlessly destroy the nest or eggs of any bird.	Condition of Certification BIO-13 includes preconstruction nest surveys, no-disturbance buffers around active nests, and monitoring of nests to minimize impacts to nesting birds; Condition of Certification BIO-6 includes a Worker Environmental Awareness Program to educate workers about compliance with environmental regulations, including Fish and Game Code section 3503.
Birds of Prey (Fish and Game Code section 3503.5)	Birds of prey are protected in California making it "unlawful to take, possess, or destroy any birds of prey (in the order Falconiformes or Strigiformes)."	Condition of Certification BIO-13 includes preconstruction nest surveys, no-disturbance buffers around active nests, and monitoring of nests to minimize impacts to nesting birds, including raptors; Condition of Certification BIO-6 includes a Worker Environmental Awareness Program to educate workers about compliance with environmental regulations, including Fish and Game Code section 3503.5; Condition of Certification BIO-25 requires preparation and implementation of an Avian Protection Plan and a monitoring study to address potential bird injury or mortality, including adaptive management actions.
Migratory Birds (Fish and Game Code section 3513)	Protects California's migratory birds by making it unlawful to take or possess any migratory nongame bird as designated in the Migratory Bird Treaty Act or any part of such migratory nongame birds.	Condition of Certification BIO-13 includes preconstruction nest surveys, no-disturbance buffers around active nests, and monitoring of nests to minimize impacts to nesting birds; Condition of Certification BIO-6 includes a Worker Environmental Awareness Program to educate workers about compliance with environmental regulations, including Fish and Game Code section 3513; Condition of Certification BIO-25 requires preparation and implementation of an Avian Protection Plan and a monitoring study to address potential bird injury or mortality, including adaptive management actions.
Significant Natural Areas (Fish and Game Code section 1930 et seq.)	Designates certain areas such as refuges, natural sloughs, riparian areas, and vernal pools as significant wildlife habitat.	There are no refuges, natural sloughs, riparian areas, and vernal pools on the solar generator site or generator tie-line alignment.
Designated Ecological Reserves (Fish and Game Code section 1580 et seq.)	The Fish and Game commission designates land and water areas as significant wildlife habitats to be preserved in natural condition for the general public to observe and study.	There are no Designated Ecological Reserves that would be affected by the project.

Applicable LORS	Description	Rationale for Compliance
California Environmental Quality Act (CEQA), CEQA Guidelines section 15380	CEQA's basic purposes are to: inform agency decision makers and the public about potential significant environmental effects of proposed activities; identify measures to avoid or reduce impacts; require these mitigation measures when feasible. CEQA defines rare species more broadly than State and federal Endangered Species Acts, such that species not protected through State or federal listing but nonetheless demonstrable as "endangered" or "rare" should also receive consideration in environmental analyses.	This section of the SA/DEIS serves to inform the decision-makers and the public of the RSEP's potential impacts to biological resources, and identifies measures to avoid or reduce those impacts; implementation of Staff's proposed Conditions of Certification BIO-1 through BIO-26 would serve to mitigate the projects impacts to biological resources below a level of significance as defined in CEQA.
Warren Alquist Act of 2005 (Public Resources Code sections 25000 et seq.)	A CEQA-equivalent process implemented by the Energy Commission.	In compliance with the Warren Alquist Act, this section of the SA/DEIS serves to inform the Energy Commission and the public of the RSEP's potential impacts to biological resources, and identifies measures to avoid or reduce those impacts; implementation of Staff's proposed Conditions of Certification BIO-1 through BIO-26 would serve to mitigate the projects impacts to biological resources below a level of significance as defined in CEQA.
Streambed Alteration Agreement (Fish and Game Code sections 1600 et seq.)	Regulates activities that may divert, obstruct, or change the natural flow or the bed, channel, or bank of any river, stream, or lake in California designated by CDFG in which there is at any time an existing fish or wildlife resource or from which these resources derive benefit. Impacts to vegetation and wildlife resulting from disturbances to waterways are also reviewed and regulated during the permitting process.	Condition of Certification BIO-22 includes measures to minimize, avoid, and compensate for impacts to jurisdictional waters of the State.
California Native Plant Protection Act of 1977 (Fish and Game Code section 1900 et seq.)	Designates State rare, threatened, and endangered plants.	Staff's proposed Conditions of Certification BIO-10 through BIO-12 include restoration and compensation for impacts to native plant communities, a Weed Management Plan, special-status plant surveys, and minimization and avoidance measures to minimize impacts to special-status plants.
California Desert Native Plants Act of 1981 (Food and Agricultural Code section 80001 et seq. and California Fish and Game Code sections 1925-1926)	Protects non-listed California desert native plants from unlawful harvesting on both public and private lands in Imperial, Inyo, Kern, Los Angeles, Mono, Riverside, San Bernardino, and San Diego counties. Unless issued a valid permit, wood receipt, tag, and seal by the commissioner or sheriff, harvesting, transporting, selling, or possessing specific desert plants is prohibited.	The proposed project does not include provisions to harvest native desert plants.

Applicable LORS	Description	Rationale for Compliance
LOCAL		
Riverside County General Plan: Land Use and Multipurpose Open Space Elements of the County General Plan (County of Riverside 2003)	Contains specific policies to preserve the character and function of open space that benefits biological resources. It also contains specific policies and goals for protecting areas of sensitive plant, soils and wildlife habitat and for assuring compatibility between natural areas and development. The RSEP area and most of eastern Riverside County is designated as Open Space Conservation in the General Plan. Although the RSEP is not within one of the 19 area plans contained within the General Plan, it is addressed in the Eastern Riverside County Desert Areas (Non-Area Plan).	Implementation of staff's proposed Conditions of Certification BIO-1 through BIO-26 would ensure that the project remains in compliance with the Riverside County General Plan regarding biological resources.

1. LORS compliance as reported here is limited only to solar generator, generator tie-line, and interconnector substation project components; LORS compliance for the OPGW component on the existing Parker-Blythe #2 transmission line is unknown.

NOTEWORTHY PUBLIC BENEFITS

The RSEP and the proposed alternatives would result in significant impacts to sensitive biological resources, and would permanently diminish the extent and value of native plant and animal communities in the region. Staff has therefore concluded that the RSEP would not provide any noteworthy public benefits related to biological resources, despite the contributions the project would make to meeting federal and State mandates for development of renewable energy resources.

PROPOSED CONDITIONS OF CERTIFICATION/MITIGATION MEASURES

The following Mitigation Measures/Conditions of Certification meet the Energy Commission's responsibility to comply with CEQA and serve as recommendations for the Energy Commission to consider in its decision to avoid or reduce the severity of impacts to less than significant and assure conformance with applicable laws, ordinances, regulations and standards (LORS). The identification of relevant and reasonable mitigation measures also conforms to National Environmental Policy Act (NEPA) requirements for BLM's and Western's analysis that can be considered in its Record of Decision. With implementation of staff's proposed conditions of certification, construction and operation of the RSEP would comply with all federal, State, and local laws, ordinances, regulations, and standards relating to biological resources. Staff recommends adoption of the following conditions of certification to mitigate potential impacts to sensitive biological resources. As described above (**C.2.5.2 Assessment of Impacts and Discussion of Mitigation**) staff concludes that these measures would reduce the project's impacts to less than significant levels under CEQA.

DESIGNATED BIOLOGIST SELECTION

BIO-1 The project owner shall assign at least one Designated Biologist to the project. The project owner shall submit the resume of the proposed Designated Biologist, with at least three references and contact information, to the Energy Commission Compliance Project Manager (CPM) for approval in consultation with Western, BLM, CDFG, and USFWS. USFWS <www.fws.gov/ventura/speciesinfo/protocols_guidelines/docs/dt> designates biologists who are approved to handle tortoises as "Authorized Biologists." Such biologists have demonstrated to USFWS that they possess sufficient desert tortoise knowledge and experience to handle and move tortoises appropriately, evaluate their health, and draw blood, and have received USFWS approval. Authorized Biologists are responsible for the implementation of all desert tortoise measures and are permitted, in turn, to approve specific monitors to handle tortoises, at their discretion. CDFG must also approve such biologists, potentially including individual approvals for monitors approved by the Authorized Biologist. Designated Biologists for the Project are the equivalent of USFWS Authorized Biologists. Only Designated Biologists and certain Biological Monitors who have been approved by the Designated Biologist shall be allowed to handle desert tortoises.

The Designated Biologist must meet the following minimum qualifications:

1. Bachelor's degree in biological sciences, zoology, botany, ecology, or a closely related field;
2. Three years of experience in field biology or current certification of a nationally recognized biological society, such as The Ecological Society of America or The Wildlife Society;
3. Have at least one year of field experience with biological resources found in or near the project area;
4. Meet the current USFWS Authorized Biologist qualifications criteria (www.fws.gov/ventura/speciesinfo/protocols_guidelines), demonstrate familiarity with protocols and guidelines for the desert tortoise, and be approved by the USFWS (note that biologists who meet previous criteria may not meet current criteria due to requirements to assess health and draw blood; biologists must obtain training such as that offered through the Desert Tortoise Conservation Center in Las Vegas); and
5. Possess a California ESA Memorandum of Understanding pursuant to Section 2081(a) for desert tortoise.

In lieu of the above requirements, the resume shall demonstrate to the satisfaction of the CPM in consultation with Western, BLM, CDFG and USFWS, that the proposed Designated Biologist or alternate has the appropriate training and background to effectively implement the conditions of certification.

Verification: No fewer than 30 days prior to construction-related ground disturbance, the Project owner shall submit the name(s) and resume(s) of the Designated

Biologists(s) along with copies of the completed USFWS Desert Tortoise Authorized Biologist Request Form(s) (www.fws.gov/ventura/speciesinfo/protocols_guidelines) to the USFWS and CPM for review and final approval in consultation with Western, BLM, and CDFG. No construction-related ground disturbance, grading, boring, or trenching shall commence until an approved Designated Biologist is available to be on site.

If a Designated Biologist needs to be replaced, the specified information of the proposed replacement must be submitted to the CPM at least 10 working days prior to the termination or release of the preceding Designated Biologist. In an emergency, the project owner shall immediately notify the CPM to discuss the qualifications and approval of a short-term replacement while a permanent Designated Biologist is proposed to the CPM for consideration.

DESIGNATED BIOLOGIST DUTIES

BIO-2 The project owner shall ensure that the Designated Biologist performs the activities described below during any site mobilization activities, construction-related ground disturbance, grading, boring, or trenching activities. The Designated Biologist may be assisted by the approved Biological Monitor(s) but remains the contact for the project owner, the CPM, Western, CDFG, BLM, and USFWS. The Designated Biologist Duties shall include, but shall not be limited to those listed below. Additional responsibilities of the Biological Monitor are set forth in Condition of Certification **BIO-9**.

1. Advise the project owner's Construction and Operation Managers on the implementation of the biological resources conditions of certification;
2. Consult on the preparation of the Biological Resources Mitigation Implementation and Monitoring Plan (BRMIMP) to be submitted by the project owner;
3. Be available to supervise, conduct, and coordinate mitigation, monitoring, and other biological resources compliance efforts, particularly in areas requiring avoidance or containing sensitive biological resources, such as special-status species or their habitat;
4. Clearly mark sensitive biological resource areas and inspect these areas at appropriate intervals for compliance with regulatory terms and conditions;
5. Inspect active construction areas where animals may have become trapped prior to construction commencing each day. At the end of each work day, inspect for the installation of structures that prevent entrapment or allow escape during periods of construction inactivity. Periodically inspect areas with high vehicle activity (e.g., parking lots) for animals in harm's way;
6. Notify the project owner and the CPM of any non-compliance with any biological resources condition of certification;

7. Respond directly to inquiries of the CPM, Western, or any other agencies regarding biological resource issues;
8. Maintain written records of the tasks specified above and those included in the BRMIMP. Summaries of these records shall be submitted in the Monthly Compliance Report and the Annual Compliance Report to the CPM;
9. Consistent with **BIO-3**, train the Biological Monitors as appropriate, and ensure their familiarity with the BRMIMP, Worker Environmental Awareness Program (WEAP) training, and USFWS guidelines on desert tortoise surveys and handling procedures <www.fws.gov/ventura/speciesinfo/protocols_guidelines>; and
10. Maintain the ability to be in regular, direct communication with representatives of CDFG, USFWS, BLM, Western, and the CPM, including notifying these agencies of dead or injured listed species and reporting special-status species observations to the California Natural Diversity Data Base consistent with Condition of Certification **BIO-22**.

Verification: The Designated Biologist shall provide copies of all written reports and summaries that document biological resources compliance activities in the Monthly Compliance Reports submitted to the CPM. If actions may affect biological resources during operation a Designated Biologist shall be available for monitoring and reporting. During project operation, the Designated Biologist shall submit record summaries in the Annual Compliance Report unless his or her duties cease, as approved by the CPM in consultation with Western, CDFG, BLM, and USFWS.

BIOLOGICAL MONITOR QUALIFICATIONS

BIO-3 The Designated Biologist shall submit the resume, at least three references, and contact information of each of the proposed Biological Monitors to the CPM. The resume shall demonstrate, to the satisfaction of the CPM, the appropriate education and experience to accomplish the assigned biological resource tasks. The Biological Monitor is the equivalent of the USFWS designated Desert Tortoise Monitor (USFWS 2008c).

The Designated Biologist will be responsible for training the Biological Monitor(s); training shall include familiarity with the conditions of certification, BRMIMP, WEAP, and USFWS guidelines on desert tortoise surveys and handling procedures <www.fws.gov/ventura/speciesinfo/protocols_guidelines>.

Verification: The project owner shall submit the specified information to the CPM for approval, in consultation with Western, CDFG, BLM, and USFWS at least 30 days prior to the start of any site mobilization or construction-related ground disturbance, grading, boring, and trenching. The Designated Biologist shall submit a written statement to the CPM confirming that individual Biological Monitor(s) has been trained including the date when training was completed. If additional biological monitors are needed during construction, the specified information shall be submitted to the CPM for approval in

consultation with Western, CDFG, BLM, and USFWS at least 10 days prior to their first day of monitoring activities.

BIOLOGICAL MONITOR DUTIES

BIO-4 The Biological Monitors shall assist the Designated Biologist in conducting surveys and in monitoring of site mobilization activities, construction-related ground disturbance, grading, boring, or trenching. The Designated Biologist shall remain the contact for the project owner the CPM, Western, CDFG, BLM, and USFWS.

Verification: The Designated Biologist shall submit in the Monthly Compliance Report to the CPM copies of all written reports and summaries that document biological resources compliance activities, including those conducted by Biological Monitors. If actions may affect biological resources during operation, a Biological Monitor, under the supervision of the Designated Biologist, shall be available for monitoring and reporting.

DESIGNATED BIOLOGIST AND BIOLOGICAL MONITOR AUTHORITY

BIO-5 The project owner's construction/operation manager shall act on the advice of the Designated Biologist and Biological Monitor(s) to ensure conformance with the biological resources conditions of certification. The Designated Biologist shall have the authority to immediately stop any activity that is not in compliance with these conditions and/or order any reasonable measure to avoid take of an individual of a listed species. If required by the Designated Biologist and Biological Monitor(s), the project owner's construction/operation manager shall halt all site mobilization, ground disturbance, grading, boring, trenching, and operation activities in areas specified by the Designated Biologist. The Designated Biologist shall:

1. Require a halt to all activities in any area when determined that there would be an unauthorized adverse impact to biological resources if the activities continued;
2. Inform the project owner and the construction/operation manager when to resume activities;
3. Notify the CPM if there is a halt of any activities and advise them of any corrective actions that have been taken or would be instituted as a result of the work stoppage; and
4. If the Designated Biologist is unavailable for direct consultation, the Biological Monitor shall act on behalf of the Designated Biologist.

Verification: The project owner shall ensure that the Designated Biologist or Biological Monitor notifies the CPM immediately (and no later than the morning following the incident, or Monday morning in the case of a weekend) of any non-compliance or a halt of any site mobilization, ground disturbance, grading, construction, and operation activities. The project owner shall notify the CPM of the circumstances and actions being taken to resolve the problem.

Whenever corrective action is taken by the project owner, a determination of success or failure will be made by the CPM in consultation with Western, CDFG, BLM, and USFWS as appropriate, within five working days after receipt of notice that corrective action is completed, or the project owner would be notified by the CPM that coordination with other agencies would require additional time before a determination can be made.

WORKER ENVIRONMENTAL AWARENESS PROGRAM (WEAP)

BIO-6 The project owner shall prepare and implement a Project-specific Worker Environmental Awareness Program (WEAP) and shall secure approval for the WEAP from the CPM in consultation with Western, CDFG, BLM, and USFWS. The WEAP shall be administered to all onsite personnel at the solar generator site, interconnector substation site, and on both transmission line alignments. The WEAP shall be administered to all surveyors, construction engineers, employees, contractors, contractor's employees, supervisors, inspectors, subcontractors, and delivery personnel. The WEAP shall be implemented during site preconstruction, construction, operation, and closure. The WEAP shall:

1. Be developed by or in consultation with the Designated Biologist and consist of an on-site or training center presentation in which supporting written material and electronic media, including photographs of protected species, is made available to all participants;
2. Discuss the locations and types of sensitive biological resources on the project site and adjacent areas, and explain the reasons for protecting these resources; provide information to participants that no snakes other reptiles, bats, or any other wildlife shall be harmed or harassed;
3. Place special emphasis on desert tortoise, burrowing owl, golden eagle, nesting birds, desert kit fox, and American badger, including information on physical characteristics, distribution, behavior, ecology, sensitivity to human activities, legal protection, penalties for violations, reporting requirements, and protection measures; for construction work on the existing 161-kB transmission line, the WEAP also shall place special emphasis on bats which may be roosting on transmission line structures;
4. Include a discussion of fire prevention measures to be implemented by workers during project activities; request workers dispose of cigarettes and cigars appropriately and not leave them on the ground or buried;
5. Describe the temporary and permanent habitat protection measures to be implemented at the project site;
6. Identify whom to contact if there are further comments and questions about the material discussed in the program;
7. Include printed training materials, including photographs and brief descriptions of desert tortoises, burrowing owls, golden eagles, nesting birds, desert kit fox, roosting bats, and American badger, including

behavior, ecology, sensitivity to human activities, legal protection, penalties for violations, reporting requirements, and protection measures;

8. Prominently display posters and descriptions in offices, conference rooms, employee break rooms, and other areas where employees may congregate, of desert tortoises, burrowing owls, golden eagles, nesting birds, desert kit fox, roosting bats, and American badger, including behavior, ecology, sensitivity to human activities, legal protection, penalties for violations, reporting requirements, and protection measures;
9. Direct all WEAP trainees to report all observations of listed species and their sign to the Designated Biologist for inclusion in the monthly compliance report; and
10. Include a training acknowledgment form to be signed by each worker indicating that they received training and shall abide by the guidelines.

The specific program can be administered by a competent individual(s) acceptable to the Designated Biologist.

Verification: At least 30 days prior to start of construction-related ground disturbance the Project owner shall provide to the CPM a copy of the WEAP for review and approval in consultation with Western, CDFG, BLM, and the USFWS. The Project owner also shall submit copies of all supporting written materials and electronic media prepared or reviewed by the Designated Biologist and a resume of the person(s) administering the program.

The project owner shall provide in the Monthly Compliance Report the number of persons who have completed the training in the prior month and a running total of all persons who have completed the training to date. At least 10 days prior to construction-related ground disturbance activities the project owner shall submit two copies of the approved final WEAP.

Throughout the life of the project, the WEAP shall be repeated annually for permanent employees, and shall be routinely administered within one week of arrival to any new construction, maintenance, or operations personnel, foremen, contractors, subcontractors, and other personnel potentially working within the project area. Upon completion of the orientation, employees shall sign a form stating that they attended the program and understand all protection measures. These forms shall be maintained by the project owner and shall be made available to the CPM upon request. Workers shall receive and be required to visibly display a hardhat sticker or certificate that they have completed the training. Training acknowledgement forms signed during construction shall be kept on file by the project owner for at least 6 months after the start of commercial operation.

During project operation, signed statements for operational personnel shall be kept on file for 6 months following the termination of an individual's employment.

BIOLOGICAL RESOURCES MITIGATION IMPLEMENTATION AND MONITORING PLAN

BIO-7 The project owner shall develop a Biological Resources Mitigation Implementation and Monitoring Plan (BRMIMP), and shall submit two copies of the proposed BRMIMP to the CPM for review and approval in consultation with Western, CDFG, BLM, and USFWS. The project owner shall implement the measures identified in the approved BRMIMP. The BRMIMP shall incorporate avoidance and minimization measures described in final versions of the Hazardous Materials Plan; the Revegetation Plan; the Weed Management Plan; the Special-Status Plant Impact Avoidance and Minimization Plan; the Desert Tortoise Translocation Plan; the Raven Monitoring, Management, and Control Plan; the Burrowing Owl Relocation and Mitigation Plan; the Streambed Management Plan; the Evaporation Pond Design, Monitoring, and Management Plan; and the Avian and Bat Protection Plan.

The BRMIMP shall be prepared in consultation with the Designated Biologist and shall include accurate and up-to-date maps depicting the location of sensitive biological resources that require temporary or permanent protection during construction and operation. The BRMIMP shall include complete and detailed descriptions of the following:

1. All biological resources mitigation, monitoring, and compliance measures proposed and agreed to by the project owner;
2. All biological resources conditions of certification identified as necessary to avoid or mitigate impacts;
3. All biological resource mitigation, monitoring, and compliance measures required in federal agency terms and conditions, such as those provided in the USFWS Biological Opinion and any additional Western or BLM stipulations;
4. All sensitive biological resources to be impacted, avoided, or mitigated by project construction, operation, and closure;
5. All required mitigation measures for each sensitive biological resource;
6. All measures that shall be taken to avoid or mitigate temporary disturbances from construction activities;
7. Duration for each type of monitoring and a description of monitoring methodologies and frequency;
8. Performance standards to be used to help decide if/when proposed mitigation is or is not successful;
9. All performance standards and remedial measures to be implemented if performance standards are not met;

10. Biological resources-related facility closure measures including a description of funding mechanism(s);
11. A process for proposing plan modifications to the CPM and any other appropriate agencies for review and approval; and
12. A requirement to submit any sightings of any special-status species that are observed on or in proximity to the project site, or during project surveys, to the California Natural Diversity Data Base (CNDDDB) per CDFG requirements.

Verification: The project owner shall submit the final BRMIMP to the CPM at least 30 days prior to start of any preconstruction site mobilization and construction-related ground disturbance, grading, boring, and trenching. The BRMIMP shall contain all of the required measures included in all biological Conditions of Certification. No construction-related ground disturbance, grading, boring, or trenching may occur prior to approval of the final BRMIMP by the CPM in consultation with Western, CDFG, BLM, and USFWS.

If any permits have not yet been received when the BRMIMP is first submitted, copies of these permits shall be submitted to the CPM within five days of their receipt, and the BRMIMP shall be revised or supplemented to reflect the permit conditions within 10 days of their receipt by the project owner. Under no circumstances shall ground disturbance proceed without implementation of all permit conditions.

To verify that the extent of construction disturbance does not exceed that described in this analysis, the project owner shall submit aerial photographs, at an approved scale, taken before and after construction to the CPM. The first set of aerial photographs shall reflect site conditions prior to any preconstruction site mobilization and construction-related ground disturbance, grading, boring, and trenching, and shall be submitted at least 60 days prior to initiation of such activities. The second set of aerial photographs shall be taken subsequent to completion of construction, and shall be submitted to the CPM no later than 90 days after completion of construction. The project owner shall also provide a final accounting of the acreages of vegetation communities/cover types present before and after construction and a depiction of the approved project boundaries superimposed on the post project aerial photograph. If final acreages and/or disturbance footprints exceed those previously approved, the CPM shall coordinate with project owner, in consultation with Western, CDFG, BLM, and USFWS to determine appropriate mitigation for such impacts. Such mitigation may exceed the requirements as outlined in these Conditions of Certification (i.e., higher mitigation ratios may be imposed as a result of consultation with the wildlife agencies).

Any changes to the approved BRMIMP (including the project footprint) must be approved by the CPM in consultation with Western, BLM, CDFG, and USFWS before such action is taken.

Implementation of BRMIMP measures (for example, construction activities that were monitored, species observed) shall be reported in the Monthly Compliance Reports by the Designated Biologist. Within 30 days after completion of project construction, the project owner shall provide to the CPM, for review and approval in consultation with Western, CDFG, BLM, and USFWS, a written construction termination report identifying

which items of the BRMIMP have been completed, a summary of all modifications to mitigation measures made during the project's preconstruction site mobilization and construction-related ground disturbance, grading, boring, and trenching, and which mitigation and monitoring items are still outstanding as well as a timeline for implementing outstanding items.

IMPACT AVOIDANCE AND MINIMIZATION MEASURES

BIO-8 The project owner shall undertake the following measures to manage the construction site and related facilities in a manner to avoid or minimize impacts to biological resources. All measures shall be subject to review and approval by the CPM.

1. Limit Disturbance Areas and Perimeter Fencing. The boundaries of all areas to be disturbed (including staging areas, access roads, and sites for temporary placement of spoils) shall be delineated with stakes and flagging prior to construction activities in consultation with the Designated Biologist. Spoils and topsoil shall be stockpiled in areas already disturbed or to be disturbed by construction, so that stockpile sites do not add to total disturbance footprint. All disturbances, project vehicles, and equipment shall be confined to the flagged areas. Parking areas, staging and disposal site locations shall similarly be located in areas without native vegetation or special-status species habitat.
2. Minimize Road Impacts. New and existing roads that are planned for construction, widening, or other improvements shall not extend beyond the flagged impact area as described above. All vehicles passing or turning around would do so within the planned impact area or in previously disturbed areas. Where new access is required outside of existing roads or the construction zone, the route shall be clearly marked (i.e., flagged and/or staked) prior to the onset of construction.
3. Minimize Traffic Impacts. Vehicular traffic during project construction and operation shall be confined to existing designated routes of travel to and from the project site, and cross country vehicle and equipment use outside designated work areas shall be prohibited. The speed limit shall not exceed 20 miles per hour within any part of the project area, maintenance roads for linear facilities, or unpaved access roads to the project site where desert tortoise clearance surveys and translocations have not been completed.
4. Monitor During Construction. Due to the possibility that desert tortoises, especially juveniles, may persist on the site after desert tortoise clearance surveys and exclusion fencing are completed, the Designated Biologist or Biological Monitor shall be present at the construction site during all project activities that have potential to disturb soil, vegetation, and wildlife. The Designated Biologist or Biological Monitor shall walk immediately ahead of equipment during brushing and grading activities. Any time over the life of the project that a desert tortoise is found within the exclusion fencing, the Designated Biologist shall immediately contact the CPM,

CDFG, and USFWS; monitor the tortoise's location and activities; and implement translocation of the animal in accordance with and the approved Desert Tortoise Translocation Plan and in consultation with the USFWS, CDFG, and CPM.

5. Minimize Impacts of Transmission/Pipeline Alignments, Roads, Staging Areas. Staging areas for construction on the solar generator site shall be within the area that has been fenced with desert tortoise exclusion fencing and cleared. For transmission line construction or other activities outside of the solar generator site, access roads, pulling sites and storage and parking areas shall be designed, installed, and maintained with the goal of minimizing impacts to native plant communities and sensitive biological resources. The Designated Biologist or Biological Monitor shall evaluate potential for special status plants or wildlife at every potential disturbance site along the lengths of both transmission lines prior to any construction-related disturbance, include access improvements. Specifically, site selection of any area to be permanently or temporarily disturbed for transmission line construction and fiber-optic installation shall avoid any desert wash, desert microphyll woodland, or any aeolian sand habitat wherever feasible. Where these sites cannot feasibly be avoided, the Designated Biologist shall outline site-specific requirements to minimize impacts to habitat and wildlife. These requirements shall include, but would not be limited to, pre-construction clearance surveys, exclusion fencing (e.g., for desert tortoise or Mojave fringe-toed lizard), on-site monitoring, and post-construction remediation.
6. Implement APLIC Guidelines. Transmission lines, fiber optic lines, and all electrical components shall be designed, installed, and maintained in accordance with the Avian Power Line Interaction Committee's (APLIC's) *Suggested Practices for Avian Protection on Power Lines* (APLIC 2006) and *Mitigating Bird Collisions with Power Lines* (APLIC 1994) to reduce the likelihood of large bird electrocutions and collisions.
7. Avoid Use of Toxic Substances. Soil bonding and weighting agents used on unpaved surfaces shall be non-toxic to wildlife and plants.
8. Minimize Lighting Impacts. Facility lighting shall be designed, installed, and maintained to prevent side casting of light towards wildlife habitat. To minimize risk of avian collisions with project features, only flashing or strobe lights shall be installed on features requiring safety lighting per FAA requirements.
9. Minimize Noise Impacts. A continuous low-pressure technique shall be used for steam blows, to the extent possible, in order to reduce noise levels in sensitive habitat proximate to the Project area. Loud construction activities (e.g., unsilenced high pressure steam blowing and pile driving, or other) shall be avoided from February 15 to April 15 when it would result in noise levels over 65 dBA in nesting habitat. Loud construction activities may be permitted from February 15 to April 15 only if the Designated

Biologist provides documentation (i.e., nesting bird data collected using methods described in **BIO-13** and maps depicting location of the nest survey area in relation to noisy construction) to the CPM indicating that no active nests would be subject to 65 dBA noise.

10. Avoid Vehicle Impacts to Desert Tortoise. Parking and storage shall occur only within the area enclosed by desert tortoise exclusion fencing to the extent feasible. No vehicles or construction equipment parked outside the fenced area shall be moved prior to an inspection of the ground beneath the vehicle for the presence of desert tortoise. If a desert tortoise is observed, it shall be left to move on its own. If it does not move within 15 minutes, a Designated Biologist or Biological Monitor under the Designated Biologist's direct supervision may remove and relocate the animal to a safe location if temperatures are within the range described in the USFWS' 2009 *Desert Tortoise Field Manual* (http://www.fws.gov/ventura/speciesinfo/protocols_guidelines). All access roads outside of the fenced project footprint shall be delineated with temporary desert tortoise exclusion fencing on either side of the access road, unless otherwise authorized by the CPM, in consultation with Western, BLM, USFWS, and CDFG.

11. Avoid Wildlife Pitfalls:

- a. Backfill Trenches. At the end of each work day, the Designated Biologist shall ensure that all potential wildlife pitfalls (trenches, bores, temporary detention basins, and other excavations) have been backfilled. If backfilling is not feasible, all trenches, bores, temporary detention basins, and other excavations shall be sloped at a 3:1 ratio at the ends to provide wildlife escape ramps, or covered completely to prevent wildlife access, or fully enclosed with desert tortoise-exclusion fencing. All trenches, bores, temporary detention basins, and other excavations outside the areas permanently fenced with desert tortoise exclusion fencing shall be inspected periodically, but no less than three times, throughout the day and at the end of each workday by the Designated Biologist or a Biological Monitor. Should a desert tortoise or other wildlife become trapped, the Designated Biologist or Biological Monitor shall remove and, if applicable, relocate it as described in the Desert Tortoise Translocation Plan. Any wildlife encountered during the course of construction shall be allowed to leave the construction area unharmed.
- b. Avoid Entrapment of Desert Tortoise. Any construction pipe, culvert, or similar structure with a diameter greater than 3 inches, stored less than 8 inches aboveground for one or more nights, shall be inspected for tortoises before the material is moved, buried, or capped. As an alternative, all such structures may be capped before being stored outside the fenced area, or placed on pipe racks.

12. Minimize Standing Water. Water applied to dirt roads and construction areas (trenches or spoil piles) for dust abatement shall use the minimal amount needed to meet safety and air quality standards in an effort to

prevent the formation of puddles, which could attract desert tortoises and common ravens to construction sites. A Biological Monitor shall patrol these areas to ensure water does not puddle and shall take appropriate action to reduce water application where necessary.

13. Dispose of Road-killed Animals. Road-killed animals or other carcasses detected on roads near the project area shall be picked up immediately and delivered to the Designated Biologist or Biological Monitor. For all road-killed species, the Designated Biologist shall retain the carcass in a freezer on-site and contact CDFG within 30 working days for guidance on disposal or storage. For any road-killed special-status species, the Biological Monitor shall contact CDFG and USFWS (for golden eagle or federally-listed species, including desert tortoise) within one working day of receipt of the carcass for guidance on disposal or storage of the carcass. The Biological Monitor shall report the special-status species record as described in Conditions of Certification **BIO-2**, **BIO-7**, and **BIO-22**.
14. Minimize Spills of Hazardous Materials. All vehicles and equipment shall be maintained in proper working condition to minimize the potential for fugitive emissions of motor oil, antifreeze, hydraulic fluid, grease, or other hazardous materials. The Designated Biologist shall be informed of any hazardous spills immediately as directed in the project Hazardous Materials Plan. Hazardous spills shall be immediately cleaned up and the contaminated soil properly disposed of at a licensed facility. Servicing of construction equipment shall take place only at a designated area. Service/maintenance vehicles shall carry a bucket and pads to absorb leaks or spills.
13. Worker Guidelines. During construction all trash and food-related waste shall be placed in self-closing containers and removed regularly from the site to prevent overflow. Workers shall not feed wildlife or bring pets to the project site, including the logistics, parking, and other ancillary areas. Except for law enforcement personnel, no workers or visitors to the site shall bring firearms or weapons. Vehicular traffic shall be confined to existing routes of travel to and from the project site, and cross country vehicle and equipment use outside designated work areas shall be prohibited. The speed limit when traveling on dirt access routes within desert tortoise habitat shall not exceed 20 miles per hour.
14. Implement Erosion Control Measures. Standard erosion control measures shall be implemented for all phases of construction and operation to prevent any sediment run-off from exposed slopes from entering state-jurisdictional streambeds within or outside the Project Disturbance Area. Sediment and other flow-restricting materials shall be moved to a location where they shall not be washed back into the stream. All disturbed soils and roads within the project site shall be stabilized to reduce erosion potential, both during and following construction, except that soil stabilizer

use may be limited in portions of roads crossing washes or stream channels consistent with applicable water quality requirements.

15. Monitor Ground-Disturbing Activities Prior to Pre-Construction Site Mobilization. If pre-construction site mobilization requires ground-disturbing activities such as for geotechnical borings or hazardous waste evaluations, a Designated Biologist or Biological Monitor shall be present to monitor any actions that could disturb soil, vegetation, or wildlife.
16. Remove Unused Material and Equipment. All unused material and equipment, including soil and rock piles, will be removed upon completion of any maintenance activities located outside the permanently fenced area.
17. Control and Regulate Fugitive Dust. To reduce the potential for the transmission of fugitive dust, the project owner shall implement dust control measures as described in staff's recommended Conditions of Certification **AQ-SC4**, **AQ-SC5**, and **AQ-SC7** in the Air Quality section of this Staff Assessment.

Verification: All mitigation measures and their implementation methods shall be included in the BRMIMP and implemented. Implementation of the measures shall be reported in the Monthly Compliance Reports by the Designated Biologist. Within 30 days after completion of project construction, the project owner shall provide to the CPM, for review and approval, a written construction termination report identifying how measures have been completed. If loud construction activities are planned between February 15 to April 15, no more than 10 days before initiation of such construction the Project owner shall provide documentation to the CPM indicating that no active nests occur in areas that would be subject to noise 65 dBA or greater.

COMPLIANCE VERIFICATION

BIO-9 The project owner shall provide the CPM, Western, BLM, CDFG, and USFWS with reasonable access to the project site and mitigation lands under the control of the project owner and shall otherwise fully cooperate with the Energy Commission's, Western's, BLM's, CDFG's, and USFWS's efforts to verify the project owner's compliance with, or the effectiveness of, mitigation measures set forth in the conditions of certification. The project owner shall hold harmless the Designated Biologist, Biological Monitor, the Energy Commission and staff, Western, BLM, CDFG, USFWS, and any other agencies with regulatory requirements addressed by the Energy Commission's sole permitting authority for any costs the project owner incurs in complying with the management measures, including stop work orders issued by the CPM, the Designated Biologist, or Biological Monitor. In addition to the duties described in **BIO-2**, the Designated Biologist shall do all of the following:

1. Notification. Notify the CPM, Western, BLM, CDFG, and USFWS at least 14 calendar days before initiating ground-disturbing activities. Immediately notify the CPM, Western, BLM, CDFG, and USFWS in writing if the project owner is not in compliance with any conditions of certification, including but not limited to any actual or anticipated failure to implement mitigation measures within the time periods specified in the conditions of

certification. CDFG shall be notified at their Southern Region Headquarters Office, 4949 Viewridge Avenue, San Diego, CA 92123; (858) 467-4201. USFWS shall be notified at the Carlsbad Fish and Wildlife Office, 6010 Hidden Valley Rd., 101, Carlsbad, CA 92011; (760) 431-9440.

2. Monitoring During Grading. Remain on site daily while grubbing and grading are taking place to avoid or minimize take of listed or special-status species, to check for compliance with all impact avoidance and minimization measures, and to check all exclusion zones to ensure that signs, stakes, and fencing are intact and that human activities are restricted in these protected zones.
3. Fence Monitoring. During construction, maintain and check desert tortoise exclusion fences on a daily basis to ensure the integrity of the fence is maintained. The Designated Biologist shall be present on site to monitor construction and determine fence placement during fence installation. During operation of the project, fence inspections shall occur at least once per month throughout the life of the project, and more frequently after storms or other events that might affect the integrity and function of desert tortoise exclusion fences. Fence repairs shall occur within two days (48 hours) of detecting problems that affect the functioning of the desert tortoise exclusion fencing. All wildlife found entrapped or dead in the fence shall be reported to the CPM, BLM, CDFG, and USFWS. Carcasses of animals entrapped in the fence shall be handled as described above in **BIO-8** paragraph 14; the Designated Biologist shall retain the carcass in a freezer on-site and contact CDFG within 30 working days for guidance on disposal or storage. For special-status species, the Biological Monitor shall contact CDFG or (for federally-listed species, including desert tortoise) within one working day.
4. Monthly Compliance Inspections. Conduct compliance inspections at a minimum of once per month after clearing, grubbing, and grading are completed and submit a monthly compliance report to the CPM. The monthly compliance report shall include all reported observations of listed species made by WEAP trainees on the site pursuant to Condition of Certification **BIO-6**.
5. Annual Listed Species Status Report. No later than January 31 of every year the project facility remains in operation, the Designated Biologist shall provide the CPM, BLM, CDFG, and USFWS an annual Listed Species Status Report, which shall include, at a minimum: 1) a general description of the status of the project site and construction/operation activities, including actual or projected completion dates, if known; 2) a copy of the table in the BRMIMP with notes showing the current implementation status of each mitigation measure; 3) an assessment of the effectiveness of each completed or partially completed mitigation measure in minimizing and compensating for project impacts, 4) recommendations on how

effectiveness of mitigation measures might be improved, and 5) a summary of any agency approved modifications to the BRMIMP.

6. Final Listed Species Mitigation Report. No later than 45 days after initiation of project operation, provide the CPM a Final Listed Species Mitigation Report that shall include, at a minimum: 1) a copy of the table in the BRMIMP with notes showing when each of the mitigation measures was implemented; 2) all available information about project-related incidental take of listed species; 3) information about other project impacts on the listed species; 4) construction dates; 5) an assessment of the effectiveness of conditions of certification in minimizing and compensating for project impacts; 6) recommendations on how mitigation measures might be changed to more effectively minimize and mitigate the impacts of future projects on the listed species; and 7) any other pertinent information, including the level of take of the listed species associated with the project.
7. Notification of Injured, Dead, or Relocated Listed Species. In the event of a sighting in an active construction area (e.g., with equipment, vehicles, or workers), injury, kill, or relocation of any listed species, the CPM, BLM, CDFG, and USFWS shall be notified immediately by phone. Notification shall occur no later than noon on the business day following the event if it occurs outside normal business hours so that the agencies can determine if further actions are required to protect listed species. Written follow-up notification via FAX or electronic communication shall be submitted to these agencies within two calendar days of the incident and include the following information as relevant:
 - a. Injured Desert Tortoise. If a desert tortoise is injured as a result of project-related activities during construction, the Designated Biologist shall immediately take it to a CDFG-approved wildlife rehabilitation and/or veterinarian clinic. Any veterinarian bills for such injured animals shall be paid by the project owner. Following phone notification as required above, the CPM, BLM, CDFG, and USFWS shall determine the final disposition of the injured animal, if it recovers. Written notification shall include, at a minimum, the date, time, location, circumstances of the incident, and the name of the facility where the animal was taken.
 - b. Desert Tortoise Fatality. If a desert tortoise is killed by project-related activities during construction or operation, or if a desert tortoise is otherwise found dead, submit a written report with the same information as an injury report. These desert tortoises shall be salvaged according to guidelines described in Salvaging Injured, Recently Dead, Ill, and Dying Wild, Free-Roaming Desert Tortoise (Berry 2001). The project owner shall pay to have the desert tortoises transported and necropsied. The report shall include the date and time of the finding or incident.
8. Stop Work Order. The CPM may issue the project owner a written stop work order to suspend any activity related to the construction or operation

of the project to prevent or remedy a violation of one or more conditions of certification (including but not limited to failure to comply with reporting, monitoring, or habitat acquisition obligations) or to prevent the illegal take of an endangered, threatened, or candidate species. The project owner shall comply with the stop work order immediately upon receipt thereof.

Verification: No later than two calendar days following the above-required notification of a sighting, kill, injury, or relocation of a listed species, the project owner shall deliver to the CPM, BLM, CDFG, and USFWS via FAX or electronic communication the written report from the Designated Biologist describing all reported incidents of the sighting, injury, kill, or relocation of a listed species, identifying who was notified and explaining when the incidents occurred. In the case of a sighting in an active construction area, the project owner shall, at the same time, submit a map (e.g., using Geographic Information Systems) depicting both the limits of construction and sighting location to the CPM, BLM, CDFG, and USFWS.

No later than January 31st of every year the RSEP facility remains in operation, provide the CPM, BLM, CDFG, and USFWS an annual Listed Species Status Report as described above, and a summary of desert tortoise exclusion fence inspections and repairs conducted in the course of the year. No later than 45 days after initiation of project operation, provide the CPM a Final Listed Species Mitigation Report as described above.

REVEGETATION PLAN AND COMPENSATION FOR IMPACTS TO NATIVE VEGETATION COMMUNITIES

BIO-10 The project owner shall provide restoration/compensation for impacts to native vegetation communities and develop and implement a Revegetation Plan for all areas subject to temporary (albeit long-term) project disturbance, including but not limited to linear features and berms of detention or debris basins, to the extent permitted by stormwater control requirements (see above, **Construction Impacts to Vegetation**). Upon completion of construction, all temporarily disturbed areas, including the logistics/lay down areas; all generator tie-line and existing 161-kV Parker-Blythe #2 transmission line tower sites, pull sites, and similar areas) shall be restored to pre-project grade and conditions. Other temporarily disturbed areas within the project area shall include, but shall not be limited to: all areas where underground infrastructure was installed, temporary access roads, construction work temporary lay-down areas, and construction equipment staging areas. The following measures shall be implemented for the revegetation effort areas not subject to the facility Landscape Plan. These measures will include:

1. Plan Details. The revegetation plan shall include at minimum: (a) locations and details for top soil storage; (b) methods to salvage and replant cacti, yucca, or other species described in BIO-12 Section E, or to plant out nursery stock of these species onto revegetation sites; (c) seed collection guidelines; (d) a schematic depicting the mitigation area; (e) time of year that the planting will occur and the methodology of the planting; (f) a description of the irrigation methodology if used; (g) measures to control

exotic vegetation on site; (h) success criteria; and (i) a detailed monitoring program. All habitats dominated by non-native species prior to project disturbance shall be revegetated using appropriate native species. This plan shall also contain contingency measures for failed restoration efforts (efforts not meeting success criteria).

2. Topsoil Salvage. Topsoil shall be stockpiled from the project site for use in revegetation of the disturbed soils. The topsoil excavated shall be segregated, kept intact, and protected, under conditions shown to sustain seed bank viability. The upper 1 inch of topsoil which contains the seed bank shall be scraped and stockpiled for use as the top-dressing for the revegetation area. An additional 6 to 8 inches of soil below the top 1 inch of soil shall also be scraped and separately stockpiled for use in revegetation areas. Topsoil shall be replaced in its original vertical orientation following ground disturbance, ensuring the integrity of the top one inch in particular. All other elements of soil stockpiling shall be conducted as described on pages 39-40 of *Rehabilitation of Disturbed Lands in California* (Newton and Claassen 2003).
3. Seed and Nursery Stock. Only seed or potted nursery stock of locally occurring native species shall be used for revegetation. Seeds shall contain a mix of short-lived early pioneer species such as native annuals and perennials and subshrubs. Seeding and planting shall be conducted as described in Chapter 5 of *Rehabilitation of Disturbed Lands in California* (Newton and Claassen 2003). A list of plant species suitable for Colorado Desert region revegetation projects, including recommended seed treatments, are included in Appendix A-9 of the same report. The list of plants observed during the special-status plant surveys of the project area can also be used as a guide to site-specific plant selection for revegetation. In conformance with BLM policy, the project owner shall include salvaged or nursery stock yucca (all species), and cacti (excluding cholla species, genus *Cylindropuntia*), in revegetation plans and implementation affecting BLM lands, as described in **BIO-12** Section E.
4. Monitoring Requirement and Success Criteria. Post-seeding and planting monitoring will be yearly and shall continue for a period of no less than 10 years or until the defined success criteria are achieved. If the survival and cover requirements have not been met, the project owner is responsible for replacement planting to achieve these requirements or other remedial action as agreed to by the CPM in consultation with BLM and Western. Replacement plants shall be monitored with the same survival and growth requirements as required for original revegetation plantings. Remediation activities (e.g., additional planting, removal of non-native invasive species, or erosion control) shall be taken during the 10-year period if necessary to ensure the success of the restoration effort. If the mitigation fails to meet the established performance criteria after the 10-year maintenance and monitoring period, monitoring and remedial activities shall extend beyond the 10-year period until the criteria are met or unless otherwise specified

by the CPM in consultation with BLM and Western. The following performance standards must be met by the end of monitoring year two:

- At least 80% of the species observed within the temporarily disturbed areas shall be native species that naturally occur in desert scrub habitats; and
 - Relative cover and density of plant species within the temporarily disturbed areas shall equal at least 60%.
5. **Replacement.** If a fire occurs in a revegetation area within the 10-year monitoring period, the owner shall be responsible for a one-time replacement. If a second fire occurs, no replanting is required, unless the fire is caused by the owner's activity (e.g., as determined by BLM or other firefighting agency investigation).

Verification: All mitigation measures and their implementation methods shall be included in the BRMIMP and implemented.

Within 90 days after completion of each year of project construction, the project owner shall provide to the CPM verification of the total vegetation acreage subject to temporary and permanent disturbance and a written report identifying which items of the Revegetation Plan have been completed, a summary of all modifications to mitigation measures made during the project's construction phase, and which items are still outstanding. To monitor and evaluate the success of the revegetation, the project owner shall submit annual reports of the revegetation including the status of the site, percent cover of native and exotics, and any remedial actions conducted by the owner to the CPM and BLM.

On January 31st of each year following construction until the completion of the revegetation monitoring specified in the Revegetation Plan, the Designated Biologist shall provide a report to the CPM that includes: a summary of revegetation activities for the year, a discussion of whether revegetation performance standards for the year were met, and recommendations for revegetation remedial action, if warranted, that are planned for the upcoming year.

WEED MANAGEMENT PLAN

BIO-11 The project owner shall prepare and implement a Weed Management Plan that meets the approval of the CPM, in consultation with Western, BLM, CDFG, and USFWS. At minimum, the Weed Management Plan shall include the following:

1. An assessment of nonnative and invasive weeds occurring onsite prior to construction activities;
2. An assessment of nonnative and invasive weeds that could be introduced into the project area;
3. A description of methods to be used to survey for the presence of introduced weeds during construction and operation;

4. Monitoring and weed control methods to be employed during operation;
5. Specific and detailed guidelines for herbicide use to prevent overspray onto surrounding areas where it would adversely affect wildlife or native plants; and
6. Reporting requirements.

The final plan shall only include weed control measures for target weeds with a demonstrated record of success, based on the best available information from sources such as: The Nature Conservancy's The Global Invasive Species Team, Cooperative Extension, California Invasive Plant Council: <http://www.cal-ipc.org/ip/management/plant_profiles/index.php>, and the California Department of Food & Agriculture Encycloweediea: <http://www.cdfa.ca.gov/phpps/ipc/encycloweediea/encycloweediea_h_p.htm>. The methods shall meet the following criteria:

Manual: well-timed removal of plants or seed heads with hand tools; seed heads and plants must be disposed of in accordance with guidelines from the Riverside County Agricultural Commissioner.

Chemical: Herbicides known to have residual toxicity, such as pre-emergents and pelts, shall not be used in natural areas or within the engineered channels. Only the following application methods may be used: wick (wiping onto leaves); inner bark injection; cut stump; frill or hack & squirt (into cuts in the trunk); basal bark girdling; foliar spot spraying with backpack sprayers or pump sprayers at low pressure or with a shield attachment to control drift, and only on windless days, or with a squeeze bottle for small infestations

In addition to describing weed eradication and control methods, and a reporting plan for weed management during and after construction, the final Weed Management Plan shall include at minimum the following Best Management Practices to prevent the spread and propagation of weeds:

- Limit the extent of any vegetation and/or ground disturbance to the absolute minimum needed, and limit ingress and egress to defined routes.
- Install and maintain vehicle wash and inspection stations and closely monitor the types of materials brought onto the site.
- Reestablish vegetation on disturbed sites with native seed mixes (measures and performance standards to be consistent with Revegetation Plan, described in Condition of Certification **BIO-10**).
- Monitoring and timely implementation of control measures to ensure early detection and eradication for weed invasions. Weed infestations must be controlled or eradicated as soon as possible upon discovery, and before they go to seed, to prevent further expansion.
- Use only weed-free straw or hay bales used for sediment barrier installations, and weed-free seed.

- Reclamation and revegetation shall occur on all temporarily disturbed areas, including, but not limited to, temporary access roads, construction work temporary lay-down areas, and staging areas.
- Control weeds in areas where irrigation and mirror washing take place.
- Prohibit on-site storage or disposal of mulch or green waste from weed material to prevent inadvertent introduction and spread of invasive plants beyond the immediate vicinity of the project area and possibly into rare plant populations off-site. Mulch or green waste shall be removed from the site in a covered vehicle to prevent seed dispersal, and transported to a licensed landfill or composting facility.
- Indicate where herbicides may be used, which herbicides, and specify techniques to be used to avoid chemical drift or residual toxicity to special-status plants, consistent with guidelines provided by the Nature Conservancy's The Global Invasive Species Team <<http://www.invasive.org/gist/products.html>>
- Avoid herbicide use or other control methods in or around Environmentally Sensitive Areas (ESAs, see Condition of Certification **BIO-12**) on-site or off-site; prevent any herbicide drift into ESAs.

Nonnative and invasive weed infestations will be flagged by the Designated Biologist or Biological Monitor and controlled, using either mechanical (hand pulling, mowing) or chemical methods as approved by the CPM and, as appropriate, Western or BLM. Only state and BLM-approved herbicides will be used, and all herbicide applicators will possess a qualified herbicide applicator license from the state. All herbicide applications will follow U.S. Environmental Protection Agency label instructions and be performed in accordance with federal, state, and local laws and regulations.

From the time construction begins and throughout the life of the project, surveying for new invasive weed populations and the monitoring of identified and treated populations shall be required within the project area. Surveying and monitoring for weed infestations shall occur at least two times per year (timed to occur early and late in the growing season). Treatment of all identified weed populations shall occur at a minimum of once annually. When no new seedlings or resprouts are observed at treated sites for three consecutive, normal rainfall years, the weed population can be considered eradicated and weed control efforts may cease for that impact site.

Verification: At least 30 days prior to the start of any project-related ground disturbance activities, the project owner shall provide the CPM and BLM with the final version of the Weed Management Plan. All modifications to the approved Weed Management Plan shall be made only after consultation with the CPM in consultation with Western, BLM, USFWS, and CDFG. Within 30 days after completion of project construction, the project owner shall provide to the CPM for review and approval, a written report identifying which items of the Weed Management Plan have been completed, a summary of all modifications to mitigation measures made during the project's construction phase, and which items are still outstanding. A summary report on

weed management on the project site shall be submitted in the Annual Compliance Report during facility operations.

SPECIAL-STATUS PLANT IMPACT AVOIDANCE, MINIMIZATION AND COMPENSATORY MITIGATION

BIO-12 This condition contains the following five sections:

- **Section A: Avoidance and Minimization Measures** describes measures to avoid and protect Harwood's milk-vetch locations on the generator tie-line alignment within 250 feet of project activities (including access roads, staging areas, laydown areas, parking and storage areas) from accidental and indirect impacts during construction, operation, and closure.
- **Section B: Conduct Further Botanical Surveys** describes guidelines for conducting summer-fall 2010 surveys to detect special-status plants that may have been missed during spring surveys on the solar generator site and generator tie-line alignment; describes guidelines for summer-fall and pre-construction spring surveys on the existing Western 161-kV Parker-Blythe transmission line alignment.
- **Section C: Mitigation Requirements for Special-Status Plants Detected** outlines the level of avoidance required for plants detected during the further surveys (Section B), based on the species' rarity and status codes. Avoidance is based on extent of local occurrences in the Project disturbance Area and, as applicable, extending onto contiguous public land.
- **Section D: Off-Site Compensatory Mitigation for Special-Status Plants** describes performance standards for mitigation for a range of options for compensatory mitigation through acquisition, restoration/enhancement, or a combination of acquisition and restoration/enhancement.
- **Section E: Conformance with BLM Plant Protection Policies** describes measures to salvage and transplant certain cacti, yucca, and other species in conformance with BLM policies.

"Project Disturbance Area" encompasses all areas to be temporarily and permanently disturbed by the Project, including the solar generator site, linear facilities, and areas disturbed by temporary access roads, fence installation, construction work lay-down and staging areas, parking, storage, or by any other activities resulting in disturbance to soil or vegetation. Nothing in this condition requires the project owner to conduct botanical surveys on private lands adjacent to the project site when the project owner has made reasonable attempts to obtain permission to enter the property for survey work but was unable to obtain such permission

The Project owner shall implement the following measures in Section A, B, C, D and E to avoid, minimize, and compensate for impacts to special-status plant species:

Section A: Special Status Plant Impact Avoidance and Minimization Measures

To protect Harwood's milk-vetch or other CNPS List 1 or List 2 plants (excluding chaparral sand-verbena) located within the project area or within 250 feet of its boundaries (including access roads, staging areas, laydown areas, parking and storage areas) from accidental and indirect impacts during construction, operation, and closure, the Project owner shall implement the following measures:

1. **Designated Botanist**. An experienced botanist who meets the qualifications described in Section **B-2** below shall oversee compliance with all special-status plant avoidance, minimization, and compensation measures described in this condition throughout construction, operation, and closure. The Designated Botanist shall oversee and train all other Biological Monitors tasked with conducting botanical survey and monitoring work.
2. **Special Status Plant Impact Avoidance and Minimization Plan**. The Project owner shall prepare and implement a Special Status Plant Impact Avoidance and Minimization Plan and shall incorporate the Plan into the BRMIMP (**BIO-7**). The Plan shall be designed to prevent direct or indirect effects of project construction and operation to CNPS List 1 and List 2 plants (excluding chaparral sand-verbena) within or within 250 feet of the project disturbance area,. The Plan shall include the following elements:
 - a. **Site Design Modifications**: Incorporate site design modifications to minimize impacts to special-status plants along the Project linears, as follows: limit the width of the work area; adjust the location of staging areas, lay downs, spur roads and poles or towers; drive and crush vegetation as an alternative to blading temporary roads to preserve soil integrity and seed banks, and adjust the alignments of roads and access points within the constraints of the ROW. These modifications shall be clearly depicted on the grading and construction plans, and on report-sized maps in the BRMIMP.
 - b. **Designate Environmentally Sensitive Areas (ESAs)**. Before construction, designate ESAs to protect all known CNPS List 1 or List 2 plant locations (excluding chaparral sand-verbena) within the project disturbance area or within 250 feet of disturbance area. The locations of ESAs shall be clearly depicted on construction drawings, which shall also include all avoidance and minimization measures on the margins of the construction plans. The boundaries of the ESAs shall provide a minimum of 250 feet buffer area between plant locations and any ground-disturbing project activity. The ESAs shall be clearly delineated in the field with fencing and signs prohibiting movement of the fence under penalty of work stoppages and additional compensatory mitigation. ESAs shall also be marked (with signage or other markers) to ensure that avoided plants are not inadvertently harmed during construction.

- c. Special-Status Plant Worker Environmental Awareness Program (WEAP). The WEAP (**BIO-6**) shall include training components specific to protection of special-status plants as outlined in this condition.
- d. Herbicide and Soil Stabilizer Drift Control Measures. Special-status plant occurrences within 250 feet of the Project Disturbance Area shall be protected from any potential herbicide and soil stabilizer drift. The Weed Control Program (**BIO-11**) shall include measures to avoid chemical drift or residual toxicity to special-status plants consistent with guidelines such as those provided by Hillmer and Liedtke (2003) and Kegley et al. (2010).
- e. Erosion and Sediment Control Measures. Erosion and sediment control measures shall avoid adverse impacts to ESAs and shall not use invasive or non-native plants in seed mixes, introduce pest plants through contaminated seed or straw, etc. These measures shall be incorporated in the Drainage, Erosion, and Sedimentation Control Plan required under **SOIL&WATER-1**.
- f. Avoid Special-Status Plant Occurrences. Areas for spoils, equipment, vehicles, and materials storage areas; parking; equipment and vehicle maintenance areas, and wash areas shall be placed at least 100 feet from the boundaries of any ESAs.
- g. Monitoring and Reporting Requirements. The Designated Botanist shall conduct weekly monitoring of the ESAs that protect special-status plant occurrences during construction and decommissioning activities.

Section B: Conduct Further Botanical Surveys

The Project owner shall conduct late-summer/fall botanical surveys for late-season special-status plants throughout the Project Disturbance Area, and shall conduct pre-construction spring surveys along the existing Western 161-kV Parker-Blythe transmission line as described below:

1. Survey Timing. To the extent feasible, surveys shall be timed to detect all special status species. Spring surveys shall be scheduled according to known flowering seasons of special-status plants of the area. To the extent feasible, late-season surveys shall be timed to detect: a) summer annuals triggered to germinate by the warm, tropical summer storms (which may occur any time between June and October), and b) fall-blooming perennials that respond to the cooler, later season storms that originate in the Pacific northwest (typically beginning in September or October). The survey dates shall be based on plant phenology and the timing of a significant storm (i.e., a 10 mm or greater rain or storm event, as measured at or within 1 mile of the Project site) if an event is recorded. Surveys for summer annuals shall be timed to occur approximately 4 to 7 weeks following a warm, tropical storm. Re-surveys shall occur as many times as necessary to ensure that surveys are conducted during the appropriate identification period for the target taxa, which may be blooms,

fruit, seed characteristics, or vegetative characteristics, depending on the taxon. However, due to the undependable nature and scattered patterns of summer and early fall rainfall, it is possible that no suitable rain event will be documented in the area. Nevertheless, the project owner shall be responsible for conducting late-season botanical surveys along washes and other lowland areas on-site due to the possibility that rainstorms in the Cady Mountains may go undetected, but may initiate summer or fall blooms.

2. Surveyor Qualifications and Training. Surveys shall be conducted by qualified botanists knowledgeable in the complex biology of the local flora and consistent with CDFG (2009) and BLM (2009b) protocols. The botanical survey crew shall be prepared to mobilize quickly to conduct appropriately timed surveys. Each field botanist shall be equipped with a GPS unit and record a complete tracklog; these data shall be compiled and submitted along with the Summer-Fall Survey Botanical Report (described below). Prior to the start of surveys, all crew members shall, at a minimum, visit target species reference sites (where available) and/or review herbarium specimens to obtain a search image.
3. Target Species. Field surveys shall be designed and scheduled to locate target species, defined as all BLM Sensitive plants, CNPS List 1 or 2 (Nature Serve rank S1 and S2) or proposed List 1 or 2 taxa, and any new reported or documented taxa. Because the potential for range extensions is unknown, the list of potentially occurring special-status plants shall include all special-status taxa known from comparable habitats within the eastern portion of the Colorado Desert in California. Determination of flowering season shall be based upon field visits to reference populations and data available online from the Consortium of California Herbaria and California Native Plant Society. The list of late-season target species shall also include taxa with bloom seasons that begin in fall and extend into the early spring as many of these are reported to be easier to detect in fall, following the start of the fall rains.
4. Survey Coverage. At a minimum, the Applicant shall conduct comprehensive surveys (i.e., 100 percent visual coverage) of the washes, dune swales, and other lowlands within the project disturbance area. In the intervening uplands (e.g., bajadas and rock outcrops) surveys shall be conducted to ensure a 25 percent visual coverage. Other special or unique habitats associated with rare plants (such as dunes, washes, and chenopod scrubs) shall also be surveyed at 100 percent visual coverage. Transects shall be “intuitive controlled” (per BLM 2009b) to ensure a focus on habitat most likely to support rare plants (such as desert washes or dunes), rather than on pre-defined, evenly-spaced survey grids.
5. Documenting Occurrences. If a special-status plant is detected, the full extent of the population on-site shall be assessed using GPS in accordance with BLM survey protocols. Additionally, the extent and density of contiguous occupied habitat within one mile of project

boundaries may be assessed at least qualitatively to facilitate an accurate estimation of the proportion of the occurrence affected by the project. For occurrences that are very dense or very large, the plant numbers may be estimated by simple sampling techniques and the survey report must provide qualitative or quantitative data describing the density and roughly mapping the extent on a topographic map. All but the smallest populations (e.g., a population occupying less than 100 square feet) shall be recorded as area polygons; small populations may be recorded as point features. All GPS-recorded occurrences shall include: the number of plants, phenology, observed threats (e.g., OHV or invasive exotics), and habitat or community type. The map of occurrences submitted with the progress reports and final botanical report shall be prepared to ensure consistency with mapping protocol and definitions of occurrences in CNDDDB: occurrences found within 0.25 miles of another occurrence of the same taxon, and not separated by significant habitat discontinuities, shall be combined into a single 'occurrence.' The Project Owner shall also submit the raw GPS shape files and metadata, and completed CNDDDB forms to CNDDDB for each occurrence as defined by CNDDDB.

Reporting. Raw GPS data, metadata, CNDDDB field forms shall be provided to the CPM within two weeks of completion of each survey. If field surveys take place during two or more phases (e.g., late summer and fall 2010; spring 2011), then a summary letter shall be submitted following each survey.

The Final Botanical Survey Report shall be prepared consistent with CDFG guidelines (CDFG 2009), and BLM guidelines (2009b) and shall include the following components:

- a. the BLM designation, NatureServe Global and State Rank of each species or taxon found (or proposed rank, or CNPS List);
- b. the number or percent of the occurrence that will be directly affected, and indirectly affected by changes in drainage patterns or altered geomorphic processes;
- c. the habitat or plant community that supports the occurrence and the total acres of that habitat or community type that occurs in the Project Disturbance Area;
- d. an indication of whether the occurrence has any local or regional significance (e.g., if it exhibits any unusual morphology, occurs at the periphery of its range in California, represents a significant range extension or disjunct occurrence, or occurs in an atypical habitat or substrate);
- e. a completed CNDDDB field form for every occurrence, and;
- f. two maps: one that depicts the raw GPS data (as collected in the field) on a topographic base map with Project features; and a second map

that follows the CNDDDB protocol for occurrence mapping, which lumps two or more occurrences of the same species within one-quarter mile or less of each other into one occurrence.

Section C: Mitigation Requirements for Special-Status Plants Detected

The Project owner shall apply the following avoidance standards to special-status plants that might be detected during the surveys described above. Avoidance and/or mitigation measures described in Section D below would reduce impacts to special-status plant species to less than significant levels.

Mitigation for CNDDDB Rank S1 and S2 Plants: If species with a CNDDDB rank of S1 or S2 (CDFG 2010b), excluding chaparral sand-verbena, are detected within the Project Disturbance Area or otherwise would be directly impacted by project activities, the Project owner shall implement avoidance measures to protect at least 75 percent of the local occurrence(s) of the species. For perennial species, the local occurrence(s) shall be measured by the number of individual plants located on the Project Disturbance Area or on contiguous public or applicant-owned lands. For annual species, the occurrence(s) shall be measured as areal extent of contiguous occupied habitat on the Project Disturbance Area and on contiguous public or applicant-owned lands. Avoidance shall include protection of the ecosystem processes essential for maintenance of the protected plant occurrence. Plants located within the ESAs established pursuant to Section A above shall be considered to be “avoided” to the extent that direct impacts on the plants are avoided and that these processes would be maintained. If special status plant occurrences are isolated by the Project from natural fluvial, aeolian, or other processes known to be necessary for their persistence or reproduction, these occurrences shall not be considered “avoided.” This evaluation shall be made by the project Botanist and CPM, in consultation with CDFG and BLM, on a case by case basis, dependent on the species and its location on the site. The Project owner shall provide compensatory mitigation as described below in Section D for Project impacts to CNDDDB Rank S1 and S2 plants that are not avoided. If the project Botanist, CPM, CDFG, and BLM agree that on-site avoidance would not allow for long-term viability of the plant occurrence(s), then compensatory mitigation may be substituted for avoidance for up to 100% of impacts to Rank S1 and S2 plants, as described below in Section D.

Mitigation for CNDDDB Rank S3 Plants: If species with a CNDDDB rank of 3 are detected within the Project Disturbance Area, no onsite avoidance or compensatory mitigation shall be required unless the occurrence has local or regional significance, in which case the plant occurrence shall be treated as a CNDDDB S2 ranked plant. A plant occurrence would be considered to have local or regional significance if:

- a. It occurs at the outermost periphery of its range in California;
- b. It occurs in an atypical habitat, region, or elevation for the taxon that suggests that the occurrence may have genetic significance (e.g., that may increase its ability to survive future threats), or;

- c. It exhibits any unusual morphology that is not clearly attributable to environmental factors that may indicate a potential new variety or sub-species.

Should CNDDDB Rank S3 plant locations meeting any of the three criteria above be found on the project site during summer or fall field surveys, mitigation requirements for those species shall be as described above for CNDDDB Rank S1 and S2 species.

Pre-Construction Notification for State- or Federal-Listed Species, or BLM Sensitive Species. If a state or federal-listed species or BLM Sensitive species is detected, the Project owner shall immediately notify the CDFG, USFWS, BLM, and the CPM.

Preservation of the Germplasm of Affected Special-Status Plants. For all impacts to CNPS List 1 or List 2 plants, excluding chaparral sand-verbena, mitigation shall include seed collection from the affected special-status plants on-site prior to construction to conserve the germplasm and provide a seed source for restoration efforts. Where construction schedules or seed availability prevents seed collection from plant locations to be impacted during a given season, seed must be collected from another portion of the project site or, as approved by the CPM in consultation with BLM's State Botanist, from public or applicant-owned lands off-site. Seed collection on public land must only be done under permit from the BLM; the project owner shall be responsible for obtaining and complying with applicable permit(s). The seed shall be collected under the supervision or guidance of a reputable seed storage facility such as the Rancho Santa Ana Botanical Garden Seed Conservation Program, San Diego Natural History Museum, or the Missouri Botanical Garden. The costs associated with the long-term storage of the seed shall be the responsibility of the Project owner. Any efforts to propagate and reintroduce special-status plants from seeds in the wild shall be carried out under the direct supervision of specialists such as those listed above and as part of a Habitat Restoration/Enhancement Plan approved by the CPM.

Section D: Off-Site Compensatory Mitigation for Special-Status Plants

Where compensatory mitigation is required under the terms of Section C, above, the Project owner shall mitigate Project impacts to CNPS List 1 or List 2 plants (excluding chaparral sand-verbena) with compensatory mitigation. Compensatory mitigation shall consist of acquisition of habitat supporting the target species, restoration/enhancement of populations of the target species, or a combination of acquisition and restoration/enhancement as provided within this Condition. Compensatory mitigation shall be at a 3:1 ratio. For annual species, compensation shall provide three acres of habitat acquired or restored/enhanced for every acre of special-status plant habitat disturbed by the Project Disturbance Area. For perennial species, compensation lands shall supporting three living plants of the same species for each plant disturbed within the project area. The Project owner shall provide funding for the acquisition and/or restoration/enhancement, initial improvement, and long-term maintenance and management of the acquired or restored lands. The actual costs to comply with this condition will vary depending on

the Project Disturbance Area, the actual costs of acquiring compensation habitat, the actual costs of initially improving the habitat, the actual costs of long-term management as determined by a Property Analysis Record (PAR) or PAR-like analysis, and other transactional costs related to the use of compensatory mitigation.

The Project owner shall comply with other related requirements in this condition:

I. Compensatory Mitigation by Acquisition: The requirements for the acquisition, initial protection and habitat improvement, and long-term maintenance and management of special-status plant compensation lands include all of the following:

Selection Criteria for Acquisition Lands. The compensation lands selected for acquisition may include any of the following three categories:

1. Occupied Habitat, No Habitat Threats: The compensation lands selected for acquisition shall be occupied by the target plant population and shall be characterized by site integrity and habitat quality that are required to support the target species, and shall be of equal or better habitat quality than that of the affected occurrence. The occurrence of the target special-status plant on the proposed acquisition lands should be viable, stable or increasing (in size and reproduction).
2. Occupied Habitat, Habitat Threats. Occupied compensation lands characterized by habitat threats may also be acquired as long as the population could be reasonably expected to recover with minor restoration (e.g., OHV or grazing exclusion, pest plant removal) and is accompanied by a Habitat Enhancement/Restoration Plan as described in Section D.II, below.
3. Unoccupied but Adjacent. The Project owner may also acquire habitat for which occupancy by the target species has not been documented, if the proposed acquisition lands are adjacent to occupied habitat. The Project owner shall provide evidence that acquisitions of such unoccupied lands would improve the defensibility and long-term sustainability of the occupied habitat by providing a protective buffer around the occurrence and by enhancing connectivity with undisturbed habitat.

Review and Approval of Compensation Lands Prior to Acquisition. The Project owner shall submit a formal acquisition proposal to the CPM describing the parcel(s) intended for purchase. This acquisition proposal shall discuss the suitability of the proposed parcel(s) as compensation lands for special-status plants in relation to the criteria listed above, and must be approved by the CPM.

Management Plan. The Project owner or approved third party shall prepare a management plan for the compensation lands in consultation with the entity that will be managing the lands. The goal of the management plan shall be to support and enhance the long-term viability of the target special-status plant occurrences. The Management Plan shall be submitted for review and approval to the CPM.

Integrating Special-Status Plant Mitigation with Other Mitigation lands. If all or any portion of the acquired Desert Tortoise, Waters of the State, or other

required compensation lands meets the criteria above for special-status plant compensation lands, the portion of the other species' or habitat compensation lands that meets any of the criteria above may be used to fulfill that portion of the obligation for special-status plant mitigation.

Compensation Lands Acquisition Requirements. The Project owner shall comply with the following requirements relating to acquisition of the compensation lands after the CPM, has approved the proposed compensation lands:

- a. Preliminary Report. The Project owner, or an approved third party, shall provide a recent preliminary title report, initial hazardous materials survey report, biological analysis, and other necessary or requested documents for the proposed compensation land to the CPM. All documents conveying or conserving compensation lands and all conditions of title are subject to review and approval by the CPM. For conveyances to the State, approval may also be required from the California Department of General Services, the Fish and Game Commission and the Wildlife Conservation Board.
- b. Title/Conveyance. The Project owner shall acquire and transfer fee title to the compensation lands, a conservation easement over the lands, or both fee title and conservation easement, as required by the CPM. Any transfer of a conservation easement or fee title must be to CDFG, a non-profit organization qualified to hold title to and manage compensation lands (pursuant to California Government Code section 65965), or to BLM or other public agency approved by the CPM. If an approved non-profit organization holds fee title to the compensation lands, a conservation easement shall be recorded in favor of CDFG or another entity approved by the CPM. If an entity other than CDFG holds a conservation easement over the compensation lands, the CPM may require that CDFG or another entity approved by the CPM, in consultation with CDFG, be named a third party beneficiary of the conservation easement. The Project owner shall obtain approval of the CPM of the terms of any transfer of fee title or conservation easement to the compensation lands.
- c. Initial Protection and Habitat Improvement. The Project owner shall fund activities that the CPM requires for the initial protection and habitat improvement of the compensation lands. These activities will vary depending on the condition and location of the land acquired, but may include trash removal, construction and repair of fences, invasive plant removal, and similar measures to protect habitat and improve habitat quality on the compensation lands. The costs of these activities are estimated to be \$750 per acre (\$250 per acre, using the estimated cost per acre for Desert Tortoise mitigation as a best available proxy, at a 3:1 ratio, but actual costs will vary depending on the measures that are required for the compensation lands). A non-profit organization, CDFG or another public agency may hold and expend the habitat improvement funds if it is qualified to manage the compensation lands (pursuant to California Government Code section 65965), if it meets the approval of the CPM in consultation with CDFG, and if it is authorized to participate in implementing the required activities on the compensation lands.

If CDFG takes fee title to the compensation lands, the habitat improvement fund must be paid to CDFG or its designee.

- d. Property Analysis Record. Upon identification of the compensation lands, the Project owner shall conduct a Property Analysis Record (PAR) or PAR-like analysis to establish the appropriate amount of the long-term maintenance and management fund to pay the in-perpetuity management of the compensation lands. The PAR or PAR-like analysis must be approved by the CPM before it can be used to establish funding levels or management activities for the compensation lands.
- e. Long-term Maintenance and Management Funding. The Project owner shall provide money to fund the long-term maintenance and management of the compensation lands. The amount of money to be paid will be determined through an approved PAR or PAR-like analysis conducted for the compensation lands. Until an approved PAR or PAR-like analysis is conducted for the compensation lands, the amount of required funding is initially estimated to be \$4,350 for every acre of compensation lands, using as the best available proxy the estimated cost of \$1,450 per acre for Desert Tortoise compensatory mitigation, at a 3:1 ratio. This amount may be revised up or down by the CPM in consultation with DFG, BLM and USFWS, based on further analysis of long-term management and maintenance costs. If compensation lands will not be identified and a PAR or PAR-like analysis completed within the time period specified for this payment (see the verification section at the end of this condition), the Project owner shall either: (i) provide initial payment equal to the amount of \$4,350 multiplied by the number of acres the Project owner proposes to acquire for compensatory mitigation; or (ii) provide security to the Energy Commission under subsection (g), "Mitigation Security," below, in an amount equal to \$4,350 multiplied by the number of acres the Project owner proposes to acquire for compensatory mitigation. The amount of the required initial payment or security for this item shall be adjusted for any change in the Project Disturbance Area as described above. If an initial payment is made based on the estimated per-acre costs, the Project owner shall deposit additional money as may be needed to provide the full amount of long-term maintenance and management funding indicated by a PAR or PAR-like analysis, once the analysis is completed and approved. If the approved analysis indicates less than \$4,350 per acquired acre (at a 3:1 ratio) will be required for long-term maintenance and management, the excess paid will be returned to the Project owner. The Project owner must obtain the CPM's approval of the entity that will receive and hold the long-term maintenance and management fund for the compensation lands. The CPM will consult with CDFG before deciding whether to approve an entity to hold the Project's long-term maintenance and management funds.

The Project owner shall ensure that an agreement is in place with the long-term maintenance and management fund holder/manager to ensure the following requirements are met:

- i. Interest. Interest generated from the initial capital long-term maintenance and management fund shall be available for reinvestment into the principal and for the long-term operation, management, and protection of the approved compensation lands, including reasonable administrative overhead, biological monitoring, improvements to carrying capacity, law enforcement measures, and any other action that is approved by the CPM and is designed to protect or improve the habitat values of the compensation lands.
- ii. Withdrawal of Principal. The long-term maintenance and management fund principal shall not be drawn upon unless such withdrawal is deemed necessary by the CPM or by the approved third-party long-term maintenance and management fund manager, to ensure the continued viability of the species on the compensation lands.
- iii. Pooling Long-Term Maintenance and Management Funds. An entity approved to hold long-term maintenance and management funds for the Project may pool those funds with similar funds that it holds from other projects for long-term maintenance and management of compensation lands for special-status plants. However, for reporting purposes, the long-term maintenance and management funds for this Project must be tracked and reported individually to the CPM.
- f. Other Expenses. In addition to the costs listed above, the Project owner shall be responsible for all other costs related to acquisition of compensation lands and conservation easements, including but not limited to the title and document review costs incurred from other state agency reviews, overhead related to providing compensation lands to CDFG or an approved third party, escrow fees or costs, environmental contaminants clearance, and other site cleanup measures.
- g. Mitigation Security. The Project owner shall provide financial assurances to the CPM to guarantee that an adequate level of funding is available to implement any of the mitigation measures required by this condition that are not completed prior to the start of ground-disturbing Project activities. Financial assurances shall be provided to the CPM in the form of an irrevocable letter of credit, a pledged savings account or another form of security ("Security") approved by the CPM. The amount of the Security shall be based upon staff's estimate of per-acre acquisition, transaction, and management costs as described in Condition of Certification **BIO-16** for each acre of occupied habitat impacted, using the estimated cost per acre for Desert Tortoise mitigation as a best available proxy, at a 3:1 ratio; see **Biological Resources Tables 6 and 9**) for every acre of habitat supporting the target special-status plant species which is significantly impacted by the project. The actual costs to comply with this condition will vary depending on the actual costs of acquiring compensation habitat, the costs of initially improving the habitat, and the actual costs of long-term management as determined by a PAR report. Prior to submitting the Security to the CPM, the Project owner shall obtain the CPM's approval of the form of the Security. The CPM may draw on the Security if the CPM determines the Project owner has

- failed to comply with the requirements specified in this condition. The CPM may use money from the Security solely for implementation of the requirements of this condition. The CPM's use of the Security to implement measures in this condition may not fully satisfy the Project owner's obligations under this condition, and the Project owner remains responsible for satisfying the obligations under this condition if the Security is insufficient. The unused Security shall be returned to the Project owner in whole or in part upon successful completion of the associated requirements in this condition.
- h. The Project owner may elect to comply with the requirements in this condition for acquisition of compensation lands, initial protection and habitat improvement on the compensation lands, or long-term maintenance and management of the compensation lands by funding, or any combination of these three requirements, by providing funds to implement those measures into the Renewable Energy Action Team (REAT) Account established with the National Fish and Wildlife Foundation (NFWF). To use this option, the Project owner must make an initial deposit to the REAT Account in an amount equal to the estimated costs (as set forth in the Security section of this condition) of implementing the requirement. If the actual cost of the acquisition, initial protection and habitat improvements, or long-term funding is more than the estimated amount initially paid by the Project owner, the Project owner shall make an additional deposit into the REAT Account sufficient to cover the actual acquisition costs, the actual costs of initial protection and habitat improvement on the compensation lands, and the long-term funding requirements as established in an approved PAR or PAR-like analysis. If those actual costs or PAR projections are less than the amount initially transferred by the applicant, the remaining balance shall be returned to the Project owner.
 - i. The responsibility for acquisition of compensation lands may be delegated to a third party other than NFWF, such as a non-governmental organization supportive of desert habitat conservation, by written agreement of the Energy Commission. Such delegation shall be subject to approval by the CPM, in consultation with CDFG, BLM and USFWS, prior to land acquisition, enhancement or management activities. Agreements to delegate land acquisition to an approved third party, or to manage compensation lands, shall be executed and implemented within 18 months of the Energy Commission's certification of the Project.

II. Compensatory Mitigation by Habitat Enhancement/Restoration: As an alternative or adjunct to land acquisition for compensatory mitigation the Project owner may undertake habitat enhancement or restoration for the target special-status plant species. Habitat enhancement or restoration activities must achieve protection at a 3:1 ratio, with improvements applied to three acres of habitat for every acre special-status plant habitat directly or indirectly disturbed by the Project Disturbance Area. Examples of suitable enhancement projects include but are not limited to the following: i) control unauthorized vehicle use into an occurrence (or pedestrian use if clearly damaging to the species); ii) control weeds that infest or pose an immediate threat to an occurrence; iii) exclude grazing by wild burros or

livestock from an occurrence; or iv) restore lost or degraded hydrologic or geomorphic functions critical to the species by restoring previously diverted flows, removing obstructions to the wind sand transport corridor above an occurrence, or increasing groundwater availability for dependent species.

If the Project owner elects to undertake a habitat enhancement project for mitigation, the project must meet the following performance standards: The proposed enhancement project shall achieve rescue of an off-site occurrence that is currently assessed, based on the NatureServe threat ranking system (Master et al. 2009; Morse et al. 2004) with one of the following threat ranks: a) long-term decline >30%; b) an immediate threat that affects >30% of the population, or c) has an overall threat impact that is High to Very High. "Rescue" would be considered successful if it achieves an improvement in the occurrence trend to "stable" or "increasing" status, or downgrading of the overall threat rank to slight or low (from "High" to "Very High").

If the Project owner elects to undertake a habitat enhancement project for mitigation, they shall submit a Habitat Enhancement/Restoration Plan to the CPM for review and approval, and shall provide sufficient funding for implementation and monitoring of the Plan. The amount of the Security shall be based upon staff's estimate of per-acre acquisition, transaction, and management costs as described in Condition of Certification **BIO-16** for each acre of occupied habitat impacted by the Project, using the estimated cost per acre for Desert Tortoise mitigation as a best available proxy, at a 3:1 ratio (see **Biological Resources Tables 6 and 9**). The amount of the security shall be adjusted based on the actual costs of implementing the enhancement, restoration and monitoring. The implementation and monitoring of the enhancement/restoration may be undertaken by an appropriate third party such as NFWF, subject to approval by the CPM. The Habitat Enhancement/Restoration Plan shall include each of the following:

1. Goals and Objectives. Define the goals of the restoration or enhancement project and a measurable course of action developed to achieve those goals. The objective of the proposed habitat enhancement plan shall include restoration of a target special-status plant occurrence that is currently threatened with a long-term decline. The proposed enhancement plan shall achieve an improvement in the occurrence trend to "stable" or "increasing" status, or downgrading of the overall threat rank to slight or low (from "High" to "Very High").
2. Historical Conditions. Provide a description of the pre-impact or historical conditions (before the site was degraded by weeds or grazing or ORV, etc.), and the desired conditions.
3. Site Characteristics. Describe other site characteristics relevant to the restoration or enhancement project (e.g., composition of native and pest plants, topography and drainage patterns, soil types, geomorphic and hydrologic processes important to the site or species).
4. Ecological Factors. Describe other important ecological factors of the species being protected, restored, or enhanced such as total population, reproduction, distribution, pollinators, etc.

5. Methods. Describe the restoration methods that will be used (e.g., invasive exotics control, site protection, seedling protection, propagation techniques, etc.) and the long-term maintenance required. The implementation phase of the enhancement must be completed within five years.
6. Budget. Provide a detailed budget and time-line, develop clear, measurable, objective-driven annual success criteria.
7. Monitoring. Develop clear, measurable monitoring methods that can be used to evaluate the effectiveness of the restoration and the benefit to the affected species. The Plan shall include a minimum of five years of quarterly monitoring, and then annual monitoring for the remainder of the enhancement project, or until the performance standards for rescue of a threatened occurrence are met, whichever comes first. At a minimum the progress reports shall include: quantitative measurements of the projects progress in meeting the enhancement project success criteria, detailed description of remedial actions taken or proposed, and contact information for the responsible parties.
8. Reporting Program. The Plan shall ensure accountability with a reporting program that includes progress toward goals and success criteria. Include names of responsible parties.
9. Contingency Plan. Describe the contingency plan for failure to meet annual goals.
10. Long-term Protection. Include proof of long-term protection for the restoration site. For private lands this would include conservations easements or other deed restrictions; projects on public lands must be contained in a Desert Wildlife Management Area, Wildlife Habitat Management Area, or other land use protections that will protect the mitigation site and target species.

Section E: Conformance with BLM Plant Protection Policies

It is BLM policy to salvage yucca and cactus plants (excluding cholla species, genus *Cylindropuntia*) and transplant them to undisturbed sites within project Rights of Way. Staff recommends conformance with policy, as follows:

- a. The project owner shall inventory all plants subject to BLM policies on all NLM lands within the Project Disturbance Area that would be removed or damaged by proposed project construction.
- b. The project owner shall prepare a Protected Plant Salvage Plan in conformance with BLM standards for review and approval by the CPM in consultation with BLM. The plan shall include detailed descriptions of proposed methods to salvage plants; transport them; store them temporarily (as needed); maintain them in temporary storage (i.e., irrigation, shade protection, etc.); proposed transplantation locations and methods for permanent relocation; proposed irrigation and maintenance methods at transplantation sites; and a monitoring plan to verify survivorship and establishment of translocated plants for a minimum of five years.

- c. Prior to initiating any ground-disturbing activities on the project site, the project owner shall implement the Protected Plant Replacement measures as approved by the CPM, in consultation with BLM's State Botanist.

Verification: The Special-Status Plant Impact Avoidance and Minimization Measures shall be incorporated into the BRMIMP as required under Condition of Certification **BIO-7**.

Implementation of the special-status plant impact avoidance and minimization measures shall be reported in the Monthly Compliance Reports prepared by the Designated Botanist. Within 30 days after completion of Project construction, the Project owner shall provide to the CPM, for review and approval in consultation with the BLM State Botanist, a written construction termination report identifying how measures have been completed.

The Project owner shall submit a monitoring report every year for the life of the project to monitor effectiveness of protection measures for all avoided special-status plants to the CPM and BLM State Botanist. The monitoring report shall include: dates of worker awareness training sessions and attendees, an inventory of the special-status plant occurrences and description of the habitat conditions, an indication of population and habitat quality trends, and description of the remedial action, if warranted and planned for the upcoming year.

Section A. No less than 30 days prior to the start of ground-disturbing activities the Project owner shall submit grading plans and construction drawings depicting the location of Environmentally Sensitive Areas and the Avoidance and Minimization Measures contained in Section A of this Condition. The project owner shall coordinate with the CPM and BLM's Wildlife Biologist to revise and finalize boundaries of the ESAs.

No less than 30 days prior to the start of ground-disturbing activities the Project owner shall submit to the CPM for review and approval, in consultation with the BLM State Botanist, the name and resume of the project's Designated Botanist. If a Designated Botanist needs to be replaced, the specified information of the proposed replacement must be submitted to BLM's Wildlife Biologist and the CPM as soon as possible prior to the termination or release of the Designated Biologist. In an emergency, the project owner shall immediately notify the BLM's Wildlife Biologist and the CPM to discuss the qualifications and approval of a short-term replacement while a permanent Designated Botanist is proposed to BLM's Wildlife Biologist and the CPM and for consideration.

No less than 30 days prior to ground-disturbing activities the Project owner shall submit a Special Status Plant Impact Avoidance and Minimization Plan to the CPM for review and approval, in consultation with the BLM State Botanist. Implementation of the impact avoidance and minimization measures shall be reported in the Monthly Compliance Reports prepared by the Designated Botanist. Within 30 days after completion of Project construction, the Project owner shall provide to the CPM, for review and approval in consultation with the BLM State Botanist, a written construction termination report identifying how measures have been completed.

The Project owner shall submit a monitoring report every year for the life of the project to monitor effectiveness of protection measures for all ESAs to the CPM and BLM State

Botanist. The monitoring report shall include: dates of worker awareness training sessions and attendees, an inventory of the special-status plant occurrences and description of the habitat conditions, an indication of population and habitat quality trends, and description of the remedial action, if warranted and planned for the upcoming year. The project owner shall coordinate with the CPM and BLM to revise and finalize monitoring reports and all reports described in this section, and shall specifically report any difficulties in meeting the protection goals and cooperatively develop adaptive measures as needed.

Section B. Raw GPS data, metadata, and CNDDDB field forms shall be submitted to the CPM within two weeks of the completion of each survey. A preliminary summary of results for the late summer/fall botanical surveys shall also be submitted to the CPM and BLM's State Botanist within two weeks following the completion of the surveys. If surveys are split into more than one period, then a summary letter shall be submitted following each survey period. The Final Summer-Fall Botanical Survey Report, GIS shape files and metadata shall be submitted to the BLM State Botanist and the CPM no less than 30 days prior to the start of ground-disturbing activities. The Final Report shall include a detailed accounting of the acreage of Project impacts to special-status plant occurrences.

Section C. The Project owner shall immediately provide written notification to the CPM, CDFG, USFWS, and BLM if it detects a State- or Federal-Listed Species, or BLM Sensitive Species at any time during its late summer/fall botanical surveys or at any time thereafter through the life of the Project, including conclusion of Project decommissioning.

Prior to construction, the project owner shall provide written verification that seed of any special status plants in the Project Disturbance Area have been collected and conveyed to a facility (as described in this measure) and that suitable long-term funding has been provided by the project owner.

Section D. If compensatory mitigation is required (based upon field survey results and mitigation strategy adopted by the project owner, as described in Sections C and D), no less than 30 days prior to the start of ground-disturbing activities, the Project owner shall submit to the CPM Security adequate to acquire compensatory mitigation lands and/or undertake habitat enhancement or restoration activities, as described in this condition.

No fewer than 90 days prior to acquisition of compensatory mitigation lands, the Project owner shall submit a formal acquisition proposal and draft Management Plan for the proposed lands to the CPM, with copies to CDFG, USFWS, and BLM, describing the parcels intended for purchase and shall obtain approval from the CPM prior to the acquisition. No fewer than 90 days prior to acquisition of compensatory mitigation lands, the Project owner shall submit to the CPM and obtain CPM approval of any agreements to delegate land acquisition to an approved third party, or to manage compensation lands; such agreement shall be executed and implemented within 18 months of the Energy Commission's certification of the Project.

The Project owner or an approved third party shall complete the acquisition and all required transfers of the compensation lands, and provide written verification to the CPM of such completion no later than 18 months after the start of Project ground-disturbing activities. If NFWF or another approved third party is being used for the acquisition, the Project owner shall ensure that funds needed to accomplish the acquisition are transferred in timely manner to facilitate the planned acquisition and to ensure the land can be acquired and transferred prior to the 18-month deadline. If habitat enhancement is proposed, no later than six months following the start of ground-disturbing activities, the Project owner shall obtain CPM approval of the final Habitat Enhancement/Restoration Plan, prepared in accordance with Section D, and submit to the CPM or a third party approved by the CPM Security adequate for long-term implementation and monitoring of the Habitat Enhancement/Restoration Plan.

Enhancement/restoration activities shall be initiated no later than 12 months from the start of construction. The implementation phase of the enhancement project shall be completed within five years of initiation. Until completion of the five-year implementation portion of the enhancement action, a report shall be prepared and submitted as part of the Annual Compliance Report. This report shall provide, at a minimum: a summary of activities for the preceding year and a summary of activities for the following year; quantitative measurements of the Project's progress in meeting the enhancement project success criteria; detailed description of remedial actions taken or proposed; and contact information for the responsible parties.

Within 18 months of ground-disturbing activities, the Project owner shall transfer to the CPM or an approved third party the difference between the Security paid and the actual costs of (1) acquiring compensatory mitigation lands, completing initial protection and habitat improvement, and funding the long-term maintenance and management of compensatory mitigation lands; and/or (2) implementing and providing for the long-term protection and monitoring of habitat enhancement or restoration activities.

Section E. The project owner shall coordinate with the CPM and BLM's Wildlife Biologist to revise and finalize all plans and reports named in this section. Verification and reporting shall be as described in BIO-10 and shall be included in reports described therein. Within 90 days after completion of each year of project construction, the project owner shall provide to the CPM verification of the numbers or acreage of plants covered in this Condition (i.e., species named in BLM and County policies) which have been removed or salvaged over the course of the year. Annual revegetation reports described in BIO-10 verification shall include summaries of salvage and planting operations and monitoring results. Compliance reports shall include summaries of written and photographic records of the plan implementation described above. Compliance reports shall be submitted annually for a period not less than 5 years to document irrigation, maintenance, and monitoring results, including plant survival.

PRE-CONSTRUCTION NEST SURVEYS AND IMPACT AVOIDANCE MEASURES FOR MIGRATORY BIRDS

BIO-13 Pre-construction nest surveys for bird species other than burrowing owls shall be conducted if construction activities will occur during the breeding period (from February 1 through August 31). Burrowing owl surveys are addressed in **BIO-19**. The Designated Biologist or Biological Monitor conducting the

surveys shall be experienced bird surveyors and familiar with standard nest-locating techniques such as those described in Martin and Guepel (1993). Surveys shall be conducted in accordance with the following guidelines. Nothing in this condition requires the project owner to conduct nesting bird surveys by entering private lands adjacent to the project site when the project owner has made reasonable attempts to obtain permission to enter the property for survey work but was unable to obtain such permission. In this situation only, the project owner may substitute binocular surveys for protocol field surveys.

1. Surveys shall cover all potential nesting habitat in the project site and within 500 feet of the boundaries of the plant site and linear facilities;
2. At least two pre-construction surveys shall be conducted, separated by a minimum 10-day interval. One of the surveys shall be conducted within the 10 days preceding initiation of construction activity. Additional follow-up surveys may be required if periods of construction inactivity exceed one week in any given area, an interval during which birds may establish a nesting territory and initiate egg laying and incubation;
3. If active nests are detected during the survey, a 500-foot no-disturbance buffer zone shall be implemented. If active raptor nests or bat maternity roosts are detected during the survey, a 1200-foot no-disturbance buffer zone shall be implemented. A monitoring plan shall be prepared and implemented to ensure no disturbance takes place within the buffer areas. This protected area surrounding the nest may be adjusted by the Designated Biologist in consultation with CDFG, USFWS, Western, and the CPM. Nest locations shall be mapped using GPS technology and submitted, along with a weekly report stating the survey results, to the CPM; and
4. The Designated Biologist shall monitor the nest until he or she determines that nestlings have fledged and dispersed. Activities that might, in the opinion of the Designated Biologist and in consultation with the CPM, disturb nesting activities shall be prohibited within the buffer zone until such a determination is made.

Verification: Prior to the start of any project-related ground disturbance activities, the project owner shall provide the CPM a letter-report describing the findings of the pre-construction nest surveys, including the time, date, and duration of the survey; identity and qualifications of the surveyor(s); and a list of species observed. If active nests are detected during the survey, the report shall include a map or aerial photo identifying the location of the nest(s) and shall depict the boundaries of the no-disturbance buffer zone around the nest(s).

DESERT TORTOISE CLEARANCE SURVEYS AND EXCLUSION FENCING

BIO-14 The project owner shall undertake appropriate measures to manage the construction site(s) and related facilities in a manner to avoid or minimize impacts to desert tortoise. Methods for clearance surveys, fence specification

and installation, tortoise handling, artificial burrow construction, egg handling and other procedures shall be consistent with those described in the USFWS' 2009 *Desert Tortoise Field Manual*

<http://www.fws.gov/ventura/speciesinfo/protocols_guidelines> or more current guidance provided by CDFG and USFWS. The project owner shall also implement all terms and conditions described in the Biological Opinion for the project to be prepared by USFWS. These measures include, but are not limited to, the following:

1. Desert Tortoise Exclusion Fence Installation. To avoid impacts to desert tortoises, permanent desert tortoise exclusion fencing shall be installed at the solar generator site along the permanent perimeter security fence and permanent access road from the security gate southward. Temporary exclusion fencing shall be installed along any additional construction site associated with the project, including the 60-acre logistics/staging area, stormwater diversion channels, and proposed generator tie-line alignment. Permanent desert tortoise exclusion fencing shall also be installed at the interconnector substation site prior to construction activities at that site. The only exception to the requirement for exclusion fencing shall be for temporary construction sites where a qualified desert tortoise monitor is on-site throughout all construction activities (e.g., transmission line construction sites). The proposed alignments for all desert tortoise exclusion fencing shall be flagged and surveyed for desert tortoise within 24 hours prior to the initiation of fence construction. Clearance surveys of the perimeter fence and utility rights-of-way alignments shall be conducted by the Designated Biologist(s) using techniques approved by the USFWS and CDFG and may be conducted in any season with USFWS and CDFG approval. Biological Monitors may assist the Designated Biologist under his or her supervision with the approval of the CPM, USFWS, and CDFG. These fence clearance surveys shall provide 100 percent coverage of all areas to be disturbed and an additional buffer approximately 90 feet wide centered on the fence alignment (i.e., 45 feet along each side of the fence line). Survey transects shall be no greater than 15 feet apart. All desert tortoise burrows, and burrows constructed by other species that might be used by desert tortoises, shall be examined to assess occupancy of each burrow by desert tortoises and handled in accordance with the USFWS' 2009 *Desert Tortoise Field Manual*. Any desert tortoise located during fence clearance surveys shall be handled only by the Designated Biologist(s) in accordance with the USFWS' 2009 *Desert Tortoise Field Manual*.
 - a. Timing, Supervision of Fence Installation. The exclusion fencing shall be installed prior to the onset of site clearing and grubbing. During construction, temporary tortoise exclusion fencing shall also be placed on access roads in tortoise habitat unless otherwise approved by the CPM, Western, BLM, USFWS, and CDFG. The fence installation shall be supervised by the Designated Biologist and monitored by the Biological Monitors to ensure the safety of any tortoise present.

- b. Fence Material and Installation. The permanent tortoise exclusionary fencing shall be constructed in accordance with the USFWS' 2009 *Desert Tortoise Field Manual* (Chapter 8 – Desert Tortoise Exclusion Fence).
 - c. Security Gates. Security gates shall be designed with minimal ground clearance to deter ingress by tortoises. The gates may be electronically activated to open and close immediately after the vehicle(s) have entered or exited to prevent the gates from being kept open for long periods of time. Cattle grating designed to safely exclude desert tortoise may be installed at the gated entries to discourage tortoises from gaining entry, to be determined by the CPM in consultation with CDFG and USFWS.
 - d. Fence Inspections. Following installation of all desert tortoise exclusion fencing (i.e., both permanent and temporary fencing), the fencing shall be regularly inspected. If tortoises were moved out of harm's way during fence construction, permanent and temporary fencing in that area shall be inspected at least two times a day for a minimum of 7 days after moving the animal to ensure a recently moved tortoise has not been trapped within the fence. Thereafter, permanent fencing shall be inspected monthly and during and within 24 hours following all major rains. Major rains are defined as a storm(s) for which surface flow is detectable within the fenced drainages. Any damage to the fencing shall be temporarily repaired immediately to keep tortoises from entering the site, and permanently repaired within 48 hours of observing damage. Monthly and post-rainfall inspections of permanent site fencing shall continue throughout the life of the project. Temporary fencing shall be inspected weekly and, where drainages intersect the fencing, during and within 24 hours following major rains. All temporary fencing shall be repaired immediately upon discovery and the Designated Biologist shall inspect the area to determine whether the damage may have permitted tortoise entry.
2. Desert Tortoise Clearance Surveys within the Plant Site. Following construction of the tortoise exclusion fencing, the solar field and adjacent fenced areas (including permanent and temporarily fenced areas) shall be cleared of tortoises by the Designated Biologist, who may be assisted by the Biological Monitors. Clearance surveys shall be conducted in accordance with the USFWS 2009 *Desert Tortoise Field Manual* (Chapter 6 – Clearance Survey Protocol for the Desert Tortoise – Mojave Population) and shall consist of at least two surveys covering 100 percent of the project area by walking transects no more than 15 feet apart. Surveys shall be repeated until two consecutive 100%-coverage surveys are completed without finding live tortoises. Transect routes on each separate survey shall be walked in different directions to allow opposing angles of observation. Clearance surveys of the power plant site may only be conducted when tortoises are most active (April through May or September through October). Surveys outside of these time periods require approval by

USFWS and CDFG. Any tortoise located during clearance surveys of the solar field site or construction areas along the transmission line route shall be relocated and monitored in accordance with the Desert Tortoise Translocation Plan (Condition of Certification **BIO-15**).

- a. Burrow Searches. During clearance surveys all desert tortoise burrows, and any burrows constructed by other species that might be used by desert tortoises, shall be examined by the Designated Biologist, who may be assisted by the Biological Monitors, to assess occupancy of each burrow by desert tortoises and handled in accordance with the USFWS' 2009 *Desert Tortoise Field Manual*. To prevent reentry by a tortoise or other wildlife, all burrows shall be collapsed once absence has been determined. Tortoises taken from burrows and from elsewhere on the solar field site or construction areas along the transmission line route shall be translocated as described in the Desert Tortoise Translocation Plan.
 - b. Burrow Excavation/Handling. All potential desert tortoise burrows located during clearance surveys shall be excavated by hand, tortoises removed, and burrows collapsed or blocked to prevent occupation by desert tortoises. All desert tortoise handling and removal, and burrow excavations, including nests, shall be conducted by the Designated Biologist, who may be assisted by a Biological Monitor in accordance with the USFWS' 2009 *Desert Tortoise Field Manual*.
3. Monitoring Following Clearing. Following the desert tortoise clearance and removal from the power plant site and utility corridor, workers and heavy equipment shall be allowed to enter the project site to perform clearing, grubbing, leveling, and trenching. A Designated Biologist shall monitor clearing and grading activities to find and move any tortoises which may have been missed during the initial tortoise clearance survey. Should a tortoise be discovered, it shall be translocated as described in the Desert Tortoise Translocation Plan to an area approved by the Designated Biologist.
 4. Relocation of Other Special-Status Species. Any special-status mammal or reptile species incidentally encountered during desert tortoise clearance surveys or monitoring (2 and 3, above), excluding American badger or desert kit fox, shall be captured and relocated to a safe, suitable area beyond the construction impact zone. If American badger or desert kit fox are encountered during the clearance surveys, they will be avoided and allowed to escape from the site as described below (Condition of Certification **BIO-20**). Any captured animal shall be maintained in a shaded, sheltered, cool (<85 degrees F) environment until relocation. If capture is not safe or feasible (e.g., for a badger) appropriate measures will be taken to encourage the animal to leave the site (including temporary exclusion fence removal, if monitored closely, per incident-specific direction from the CPM and cooperating agencies). The Designated Biologist shall coordinate with staff and CDFG biologists in the transport and relocation of any special-status animals encountered during

project surveys, construction, or operation. A written report documenting any animals relocated shall be provided to the CPM within 30 days of relocation.

5. **Reporting.** The Designated Biologist shall record the following information for any desert tortoises handled: a) the locations (narrative and maps) and dates of observation; b) general condition and health, including injuries, state of healing and whether desert tortoise voided their bladders; c) location moved from and location moved to (using GPS technology); d) gender, carapace length, and diagnostic markings (i.e., identification numbers or marked lateral scutes); e) ambient temperature when handled and released; and f) digital photograph of each handled desert tortoise. Desert tortoises moved from within project areas shall be monitored in accordance with the Desert Tortoise Translocation Plan.

Verification: All mitigation measures and their implementation methods shall be included in the BRMIMP and implemented by the project owner. Implementation of the measures shall be reported in the Monthly Compliance Reports by the Designated Biologist. Within 30 days after completion of desert tortoise clearance surveys the Designated Biologist shall submit a report to the CPM, Western, BLM, USFWS, and CDFG describing implementation of each of the mitigation measures listed above. The report shall include the desert tortoise survey results, capture and release locations of any relocated desert tortoises or other animals, and any other information needed to demonstrate compliance with the measures described above.

DESERT TORTOISE TRANSLOCATION PLAN

BIO-15 The project owner shall prepare and implement a final Desert Tortoise Translocation Plan (Plan) in conformance with standards and guidelines described in *Translocation of Desert Tortoises (Mojave Population) From Project Sites: Plan Development Guidance* (USFWS August 2010), any more current guidance or recommendations as available from CDFG or USFWS, and meets the approval of the CPM in consultation with Western, BLM, USFWS, and CDFG. The goal of the Plan shall be to safely exclude desert tortoises from within the fenced project area and translocate them to suitable habitat capable of supporting them, while minimizing stress and potential for disease transmission. The final Plan shall be based on the draft Desert Tortoise Relocation/Translocation Plan prepared by the applicant and shall include all revisions deemed necessary by USFWS, CDFG, and the CPM, in consultation with Western and BLM. The Plan shall include but not be limited to, a list of the authorized handlers, protocols for disease testing and assessing tortoise health, proposed translocation locations and procedures, schedule of translocations, a habitat assessment of translocation lands, monitoring of translocated tortoise(s), reporting, and contingency planning (e.g., handling an injured or diseased tortoise).

Verification: Within 30 days of publication of the Energy Commission License Decision the project owner shall provide the CPM with the final version of a Desert Tortoise Translocation Plan that is consistent with all terms and conditions of the Biological Opinion and Incidental Take Permits, both yet to be issued. The Plan shall

not be accepted as “final” until it has been reviewed and approved by the CPM, USFWS, and CDFG in consultation with Western and BLM. Any modifications to the approved final Plan shall be made only with written approval by the CPM, USFWS, and CDFG in consultation with Western and BLM.

Within 30 days after initiation of translocation activities, the Designated Biologist shall provide to the CPM for review and approval in consultation with Western, USFWS, BLM, and CDFG, a written report identifying which items of the final Desert Tortoise Translocation Plan have been completed, and a summary of any modifications to measures made during implementation of the Plan. Written monthly progress reports shall be provided to the CPM for the duration of the Plan implementation. Progress reports shall be made available to Western, BLM, CDFG, and USFWS upon request.

DESERT TORTOISE COMPENSATORY MITIGATION

BIO-16 The project owner shall provide compensatory mitigation acreage of 1,988 acres of desert tortoise habitat lands, adjusted to reflect the final project footprint, as specified in this condition. A portion of this compensation land may consist of land currently held by the project owner, pending analysis of its suitability (see Selection Criteria, below), as discussed in the analysis of impacts to desert tortoise, above. In addition, the project owner shall provide funding for initial improvement and long-term maintenance, enhancement, and management of the acquired lands for protection and enhancement of desert tortoise populations, and comply with other related requirements of this condition. This acreage was calculated as follows: Impacts to the solar generator site and existing 161-kV Parker-Blythe transmission line shall be compensated at a 1:1 ratio. Impacts along the generator tie-line and at the interconnector substation shall be compensated at a 3:1 ratio (see **Biological Resources Table 8**). These impact acreages are to be adjusted to reflect the final project footprint. For purposes of this condition, the Project footprint means all lands disturbed in the construction and operation of the Project, including all linear project components, as well as undeveloped areas inside the Project’s boundaries that will no longer provide viable long-term habitat for the desert tortoise.

Costs of these requirements are estimated to be \$5,076,447.00 based on the acquisition of 1,988 acres (see **Biological Resources Tables 6** and **9** for a complete breakdown of costs and acreage).

As many as 99 acres (based on staff’s estimate of generator tie-line and interconnector substation acreage on public land) of the compensation lands requirement, plus unspecified acreage along the existing 161-kV Parker-Blythe #2 transmission line alignment, may be satisfied by applicant’s compliance with the desert tortoise habitat acquisition or enhancement requirements of BLM, to be calculated as an acre-for-acre offset in the Energy Commission requirement for mitigation provided to satisfy BLM’s requirements. For purposes of this paragraph, credit will be given for BLM-required mitigation without regard to whether BLM uses the mitigation funds for habitat acquisition or for enhancement projects to benefit the species.

The project owner shall provide financial assurances as described below in the amount of \$5,076,447. In lieu of acquiring lands itself, the Project owner may satisfy the requirements of this condition by depositing funds into a Renewable Energy Action Team (REAT) Account established with the National Fish and Wildlife Foundation (NFWF), as described below. If the Project owner elects to establish a REAT NFWF Account and have NFWF and the agencies complete the required habitat compensation, then the total estimated cost of complying with this condition is \$5,213,088.41. The amount of security or NFWF deposit shall be adjusted up or down to reflect any revised cost estimates recommended by REAT.

The actual costs to comply with this condition will vary depending on the final footprint of the Project, the costs of acquiring compensation habitat, the costs of initially improving the habitat, and the actual costs of long-term management as determined by a Property Analysis Report or similar analysis (below). The 1,988 acre habitat requirement, and associated funding requirements based on that acreage, shall be adjusted up or down if there are changes in the final footprint of the project or the associated costs of evaluation, acquisition, management, and other factors listed in **Biological Resources Tables 6 and 10**. Regardless of actual cost, the project owner shall be responsible for funding all requirements of this condition.

COMPENSATORY MITIGATION LAND ACQUISITION

1. Method of Acquisition. Compensation lands shall be acquired by either of the two options listed below. Regardless of the method of acquisition, the transaction shall be complete only upon completion of all terms and conditions described in this Condition of Certification.
 - a. The project owner transfer title and/or conservation easement of compensation lands to a state or federal land management agency or to a third-party non-profit land management organization, as approved by the CPM in consultation with BLM, CDFG, and USFWS; staff recommends transfer in fee title to the lands to CDFG under terms approved by CDFG. Alternatively, a CDFG-approved non-profit organization qualified pursuant to California Government Code section 65965 may hold the fee title or a conservation easement over the lands. In the event an approved non-profit holds title, a conservation easement shall be recorded in favor of CDFG in a form approved by CDFG; in the event an approved non-profit holds a conservation easement over the lands, CDFG shall be named third party beneficiary; or
 - b. The Project owner shall deposit funds into a project-specific subaccount within the REAT Account established with the NFWF, in the amount as indicated in **Biological Resources Tables 6 and 10** (adjusted to reflect final project footprint and any applicable REAT adjustments to costs).

2. Selection Criteria for Compensation Lands. Pending a review of the selection criteria below, staff has tentatively determined, in consultation with Western, CDFG, BLM, and USFWS, that applicant-owned land contiguous to the solar generator site would meet criteria as mitigation lands to partially satisfy this Condition of Certification (see discussion of “location of acquired habitat compensation lands” under Desert Tortoise, in the Assessment of Impacts and Discussion of Mitigation section, above). Any additional or alternate compensation lands selected for acquisition to meet Energy Commission and CESA requirements shall be equal to or better than the quality and function of the habitat impacted and shall:
 - a. be within the Colorado Desert Recovery Unit, with potential to contribute to desert tortoise habitat connectivity and build linkages between desert tortoise designated critical habitat, known populations of desert tortoise, and/or other preserve lands;
 - b. provide habitat for desert tortoise with capacity to regenerate naturally when disturbances are removed;
 - c. be near larger blocks of lands that are either already protected or planned for protection, or which could feasibly be protected long-term by a public resource agency or a non-governmental organization dedicated to habitat preservation;
 - d. be contiguous and biologically connected to lands currently occupied by desert tortoise, ideally with populations that are stable, recovering, or likely to recover;
 - e. not have a history of intensive recreational use or other disturbance that might cause future erosional damage or other habitat damage, and make habitat recovery and restoration infeasible;
 - f. not be characterized by high densities of invasive species, either on or immediately adjacent to the parcels under consideration, that might jeopardize habitat recovery and restoration; and
 - g. not contain hazardous wastes that cannot be removed to the extent that the site could not provide suitable habitat; and
 - h. have water and mineral rights included as part of the acquisition, unless the CPM, in consultation with CDFG, BLM and USFWS, agrees in writing to the acceptability of land without these rights.
3. Review and Approval of Compensation Lands Prior to Acquisition. The project owner shall submit a formal acquisition proposal to the CPM describing the parcel(s) intended for purchase. This acquisition proposal shall discuss the suitability of the proposed parcel(s) as compensation lands for desert tortoise in relation to the criteria listed above and must be

approved by the CPM. The CPM will share the proposal with and consult with Western, CDFG, BLM and the USFWS before deciding whether to approve or disapprove the proposed acquisition.

4. Compensation Lands Acquisition Conditions: The project owner shall comply with the following conditions relating to acquisition of the compensation lands after the CPM, in consultation with Western, CDFG, BLM and the USFWS, have approved the proposed compensation lands:
 - a. Preliminary Report: The Project owner, or approved third party, shall provide a recent preliminary title report, initial hazardous materials survey report, biological analysis, and other necessary or requested documents for the proposed compensation land to the CPM. All documents conveying or conserving compensation lands and all conditions of title are subject to review and approval by the CPM, in consultation with Western, CDFG, BLM and the USFWS. For conveyances to the State, approval may also be required from the California Department of General Services, the Fish and Game Commission, and the Wildlife Conservation Board.
 - b. Title/Conveyance: The Project owner shall acquire and transfer fee title to the compensation lands, a conservation easement over the lands, or both fee title and conservation easement as required by the CPM in consultation with CDFG. Any transfer of a conservation easement or fee title must be to CDFG, a non-profit organization qualified to hold title to and manage compensation lands (pursuant to California Government Code section 65965), or to BLM or other public agency approved by the CPM in consultation with CDFG. If an approved non-profit organization holds fee title to the compensation lands, a conservation easement shall be recorded in favor of CDFG or another entity approved by the CPM. If an approved non-profit holds a conservation easement, CDFG shall be named a third party beneficiary. If an entity other than CDFG holds a conservation easement over the compensation lands, the CPM may require that CDFG or another entity approved by the CPM, in consultation with CDFG, be named a third party beneficiary of the conservation easement. The Project owner shall obtain approval of the CPM, in consultation with CDFG, of the terms of any transfer of fee title or conservation easement to the compensation lands.
 - c. Property Analysis Record. Upon identification of the compensation lands, the Project owner shall conduct a Property Analysis Record (PAR) or PAR-like analysis to establish the appropriate amount of the long-term maintenance and management fund to pay the in-perpetuity management of the compensation lands. The PAR or PAR-like analysis must be approved by the CPM, in consultation with CDFG, before it can be used to establish funding levels or management activities for the compensation lands.

5. Compensation Lands Acquisition Costs: The Project owner shall pay all other costs related to acquisition of compensation lands and conservation easements. In addition to actual land costs, these acquisition costs shall include but shall not be limited to the items listed below. Management costs including site cleanup measures are described separately, in the following section.
 - a. Level 1 Environmental Site Assessment;
 - b. Appraisal;
 - c. Title and document review costs;
 - d. Expenses incurred from other state, federal, or local agency reviews;
 - e. Closing and escrow costs;
 - f. Overhead costs related to providing compensation lands to CDFG or an approved third party;
 - g. Biological survey(s) to determine mitigation value of the land; and
 - h. Agency costs to accept the land (e.g., writing and recording of conservation easements; title transfer).

COMPENSATORY MITIGATION LAND IMPROVEMENT

1. Land Improvement Requirements: The Project owner shall fund activities that the CPM, in consultation with Western, CDFG, USFWS and BLM, requires for the initial protection and habitat improvement of the compensation lands. These activities will vary depending on the condition and location of the land acquired, but may include surveys of boundaries and property lines, installation of signs, trash removal and other site cleanup measures, construction and repair of fences, invasive plant removal, removal of roads, and similar measures to protect habitat and improve habitat quality on the compensation lands.

The costs of these activities are estimated at \$250 an acre, but will vary depending on the measures that are required for the compensation lands. A non-profit organization, CDFG or another public agency may hold and expend the habitat improvement funds if it is qualified to manage the compensation lands (pursuant to California Government Code section 65965), if it meets the approval of the CPM in consultation with CDFG, and if it is authorized to participate in implementing the required activities on the compensation lands. If CDFG takes fee title to the compensation lands, the habitat improvement fund must be paid to CDFG or its designee.

COMPENSATORY MITIGATION LAND LONG-TERM MANAGEMENT

1. Long-term Management Requirements: Long-term management is required to ensure that the compensation lands are managed and

maintained to protect and enhance habitat for desert tortoise. Management activities may include maintenance of signs, fences, removal of invasive weeds, monitoring, security and enforcement, and control or elimination of unauthorized use.

2. Long-term Management Plan. The project owner shall pay for the preparation of a Management Plan for the compensation lands. The Management Plan shall reflect site-specific enhancement measures on the acquired compensation lands. The plan shall be submitted for approval of the CPM, in consultation with Western, CDFG, BLM and USFWS.
3. Long-Term Maintenance and Management Funding. The Project owner shall provide money to fund the long-term maintenance and management of the compensation lands. The amount of money to be paid will be determined through an approved PAR or PAR-like analysis conducted for the compensation lands. The amount of required funding is initially estimated to be \$1,450 for every acre of compensation lands. If compensation lands will not be identified and a PAR or PAR-like analysis completed within the time period specified for this payment (see the verification section at the end of this condition), the Project owner shall provide initial payment of \$2,882,600.00 calculated at \$1,450 an acre for 1,988 into an account for long-term maintenance and management of compensation lands. The amount of the required initial payment or security for this item shall be adjusted for any change in the Project footprint as described above. If an initial payment is made based on the estimated per-acre costs, the project owner shall deposit additional money as may be needed to provide the full amount of long-term maintenance and management funding indicated by a PAR or PAR-like analysis, once the analysis is completed and approved. If the approved analysis indicates less than \$1,450 an acre will be required for long-term maintenance and management, the excess paid will be returned to the Project owner.

The project owner must obtain the CPM's approval of the entity that will receive and hold the long-term maintenance and management fund for the compensation lands. The CPM will consult with the project owner and CDFG before deciding whether to approve an entity to hold the project's long-term maintenance and management funds on any lands. The CPM, in consultation with the project owner and CDFG, may designate another state agency or non-profit organization to hold the long-term maintenance and management fee if the organization is qualified to manage the compensation lands in perpetuity.

If CDFG takes fee title to the compensation lands, CDFG shall determine whether it will hold the long-term management fee in the special deposit fund, leave the money in the REAT Account, or designate another entity to manage the long-term maintenance and management fee for CDFG and with CDFG supervision.

The Project owner shall ensure that an agreement is in place with the long-term maintenance and management fee holder/manager to ensure the following conditions:

- i. Interest. Interest generated from the initial capital shall be available for reinvestment into the principal and for the long-term operation, management, and protection of the approved compensation lands, including reasonable administrative overhead, biological monitoring, improvements to carrying capacity, law enforcement measures, and any other action approved by CDFG designed to protect or improve the habitat values of the compensation lands.
- ii. Withdrawal of Principal. The long-term maintenance and management fee principal shall not be drawn upon unless such withdrawal is deemed necessary by the CPM, in consultation with CDFG, or the approved third-party long-term maintenance and management fee manager to ensure the continued viability of the species on the compensation lands. If CDFG takes fee title to the compensation lands, monies received by CDFG pursuant to this provision shall be deposited in a special deposit fund established solely for the purpose to manage lands in perpetuity unless CDFG designates NFWF or another entity to manage the long-term maintenance and management fee for CDFG.
- iii. Pooling Funds. A CPM- approved non-profit organization qualified to hold long-term maintenance and management fees solely for the purpose to manage lands in perpetuity, may pool the fund with other funds for the operation, management, and protection of the compensation lands for local populations of desert tortoise. However, for reporting purposes, the long-term maintenance and management fee fund must be tracked and reported individually to the CDFG and CPM.
- iv. Reimbursement Fund. The project owner shall provide reimbursement to CDFG or an approved third party for reasonable expenses incurred during title, easement, and documentation review; expenses incurred from other State or State-approved federal agency reviews; and overhead related to providing compensation lands.

COMPENSATORY MITIGATION LAND SECURITY

1. Compensation Mitigation Security: The project owner shall provide security sufficient for funding acquisition, improvement, and long-term management of desert tortoise compensation land. Financial assurance can be provided to the CPM in the form of an irrevocable letter of credit, a pledged savings account or another form of security ("Security"). Prior to submitting the Security to the CPM, the Project owner shall obtain the CPM's approval, in consultation with CDFG, BLM and the USFWS, of the form of the Security.

The security amount shall be based on the estimates provided in **Biological Resources Tables 6 and 9**. This amount shall be updated and verified prior to payment and shall be adjusted to reflect actual costs or more current estimates as agreed upon by the REAT agencies.

The Project owner shall provide verification that financial assurances have been established to the CPM with copies of the document(s) to BLM, CDFG and the USFWS, to guarantee that an adequate level of funding is available to implement any of the mitigation measures required by this condition that are not completed prior to the start of ground-disturbing activities described in Section A of this condition.

In the event that the project owner defaults on the Security, the CPM may use money from the Security solely for implementation of the requirements of this condition. The CPM's use of the security to implement measures in this condition may not fully satisfy the Project owner's obligations under this condition. Any amount of the Security that is not used to carry out mitigation shall be returned to the Project owner upon successful completion of the associated requirements in this condition.

Security for the requirements of this condition shall be provided in the amount of \$5,076,447.00 (or \$5,213,088.41 if the project owner elects to use the REAT Account with NFWF pursuant to paragraph 2 of this condition, below). The Security is calculated in part from the items that follow but adjusted as specified below (consult **Biological Resources Tables 6 and 9** for the complete breakdown of estimated costs). However, regardless of the amount of the security or actual cost of implementation, the project owner shall be responsible for implementing all aspects of this condition.

- i. land acquisition costs for compensation land, calculated at \$500/acre;
- ii. Site assessments, appraisals, biological surveys, transaction closing and escrow costs, calculated as \$18,000 total per parcel (presuming 160 acres per parcel);
- iii. Initial site clean-up, restoration, or enhancement, calculated at \$250/acre;
- iv. Third-party and agency administrative transaction costs and overhead, calculated as percentages of land cost;
- v. Long-term management and maintenance fund, calculated at \$1,450 per acre; and
- vi. NFWF fees to establish a project-specific account; manage the sub-account for acquisition and initial site work; and manage the sub-account for long term management and maintenance.

2. The project owner may elect to comply with some or all of the requirements in this condition by providing funds to implement the requirements into the Renewable Energy Action Team (REAT) Account established with the National Fish and Wildlife Foundation (NFWF). To use this option, the Project owner must make an initial deposit to the REAT Account in an amount equal to the estimated costs of implementing the requirement (as set forth in the Security section of this condition, paragraph 1, above). If the actual cost of the acquisition, initial protection and habitat improvements, long-term funding or other cost is more than the estimated amount initially paid by the project owner, the project owner shall make an additional deposit into the REAT Account sufficient to cover the actual acquisition costs, the actual costs of initial protection and habitat improvement on the compensation lands, the long-term funding requirements as established in an approved PAR or PAR-like analysis, or the other actual costs that are estimated in the table. If those actual costs or PAR projections are less than the amount initially transferred by the applicant, the remaining balance shall be returned to the project owner.
3. The responsibility for acquisition of compensation lands may be delegated to a third party other than NFWF, such as a non-governmental organization supportive of desert habitat conservation, by written agreement of the Energy Commission. Such delegation shall be subject to approval by the CPM, in consultation with CDFG, BLM and USFWS, prior to land acquisition, enhancement or management activities. Agreements to delegate land acquisition to an approved third party, or to manage compensation lands, shall be executed and implemented within 18 months of the Energy Commission's certification of the project.
5. The project owner may request the CPM to provide it with all available information about any funds held by the Energy Commission, CDFG, or NFWF as project security, or funds held in a NFWF sub-account for this project, or other project-specific account held by a third party. The CPM shall also fully cooperate with any independent audit that the project owner may choose to perform on any of these funds.

Verification: The project owner shall provide the CPM with written notice of intent to start ground disturbance at least 30 days prior to the start of ground-disturbing activities on the project site.

If the mitigation actions required under this condition are not completed at least 30 days prior to the start of ground-disturbing activities, the Project owner shall provide verification to the CPM and CDFG that an approved Security has been established in accordance with this condition of certification no later than 30 days prior to beginning Project ground-disturbing activities. Financial assurance can be provided to the CPM in the form of an irrevocable letter of credit, a pledged savings account or another form of security ("Security"). Prior to submitting the Security to the CPM, the project owner shall obtain the CPM's approval, in consultation with Western, CDFG, BLM and the USFWS, of the form of the Security. The project owner, or an approved third party, shall complete and provide written verification to the CPM, Western, CDFG, BLM and USFWS of the

compensation lands acquisition and transfer within 18 months of the start of Project ground-disturbing activities.

No later than 12 months after the start of ground-disturbing project activities, the project owner shall submit a formal acquisition proposal to the CPM describing the parcels intended for purchase or transfer, and shall obtain approval from the CPM, in consultation with Western, CDFG, BLM and USFWS, prior to the acquisition. If NFWF or another approved third party is handling the acquisition, the project owner shall fully cooperate with the third party to ensure the proposal is submitted within this time period. The project owner or an approved third party shall complete the acquisition and all required transfers of the compensation lands, and provide written verification to the CPM, Western, CDFG, BLM and USFWS of such completion, no later than 18 months after the issuance of the Energy Commission Decision. If NFWF or another approved third party is being used for all or part of the acquisition, the project owner shall ensure that funds needed to accomplish the acquisition are transferred in timely manner to facilitate the planned acquisition and to ensure the land can be acquired and transferred prior to the 18-month deadline.

The project owner shall complete and submit to the CPM a PAR or PAR-like analysis no later than 60 days after the CPM approves compensation lands for acquisition associated with any phase of construction. The project owner shall fully fund the required amount for long-term maintenance and management of the compensation lands for that phase of construction no later than 30 days after the CPM approves a PAR or PAR-like analysis of the anticipated long-term maintenance and management costs of the compensation lands. Written verification shall be provided to the CPM and CDFG to confirm payment of the long-term maintenance and management funds.

No later than 60 days after the CPM determines what activities are required to provide for initial protection and habitat improvement on the compensation lands for any phase of construction, the project owner shall make funding available for those activities and provide written verification to the CPM of what funds are available and how costs will be paid. Initial protection and habitat improvement activities on the compensation lands for that phase of construction shall be completed, and written verification provided to the CPM, no later than six months after the CPM's determination of what activities are required on the compensation lands.

The project owner, or an approved third party, shall provide the CPM, Western, CDFG, BLM and USFWS with a management plan for the compensation lands within 180 days of the land or easement purchase, as determined by the date on the title. The CPM, in consultation with Western, CDFG, BLM and the USFWS, shall approve the management plan after its content is acceptable to the CPM.

Within 90 days after completion of all project related ground disturbance, the project owner shall provide to the CPM, CDFG, BLM and USFWS an analysis, based on aerial photography, with the final accounting of the amount of habitat disturbed during Project construction. If this analysis shows that more lands were disturbed than was anticipated in this condition, the project owner shall provide the Energy Commission with additional compensation lands and funding commensurate with the added impacts and applicable mitigation ratios set forth in this condition. A final analysis of all project related ground

disturbance may not result in a reduction of compensation requirements if the deadlines established under this condition for transfer of compensation lands and funding have passed prior to completion of the analysis.

RAVEN MONITORING, MANAGEMENT, AND CONTROL PLAN

BIO-17 The project owner shall prepare and implement a Raven Monitoring, Management, and Control Plan (Raven Plan) that shall be consistent with the most current USFWS-approved raven management guidelines and that meets the approval of the CPM in consultation with Western, BLM, USFWS, and CDFG. The draft Raven Plan submitted by the applicant (Appendix B of CH2MHill 2010c) shall provide the basis for the final plan, subject to review, revisions and approval from the CPM in consultation with Western, BLM, USFWS, and CDFG.. The purpose of the plan shall be to avoid any Project-related increases in raven numbers or activity during construction, operation, and decommissioning. The Plan shall address all project components and their potential effects on raven numbers and activity, including but not limited to the solar generator site, temporary logistics and lay down areas, generator tie-line alignment, distribution line, and fiber optic OPGW installation on the Parker-Blythe #2 transmission line. The threshold for implementation of raven control measures shall be any increases in raven numbers from baseline conditions, as detected by monitoring to be implemented pursuant to the Plan. Regardless of raven monitoring results, the project owner shall be responsible for all other aspects of raven management described in the Plan, including avoidance and minimization of project-related trash, water sources, or perch/roost sites that could contribute to increased raven numbers, throughout the life of the project. In addition, to offset the cumulative contributions of the Project to desert tortoise from increased raven numbers, the Project owner shall also contribute to the USFWS Regional Raven Management Program. The Project owner shall do all of the following:

1. Prepare and Implement a Raven Management Plan that shall include, but shall not be limited to the following components:
 - a. Identify conditions potentially associated with the Project that might provide raven subsidies or attractants;
 - b. Describe management practices to avoid or minimize conditions that might increase raven numbers and predatory activities;
 - c. Specify a program to monitor raven presence in the Project vicinity and detect any increase in numbers or activity;
 - d. Specify raven activity thresholds for implementation of control measures;
 - e. Describe control practices for ravens to be implemented as needed based on that monitoring results;
 - f. Address monitoring and nest removal during construction and for the life of the Project; and

- g. Describe reporting schedules and requirements; for the first year of reporting the project owner shall provide quarterly reports describing implementation of the Plan; thereafter the reports shall be submitted annually for the life of the project.
 2. Contribute to the USFWS Regional Raven Management Program. The project owner shall submit payment to the project sub-account of the REAT Account held by the National Fish and Wildlife Foundation (NFWF) to support the USFWS Regional Raven Management Program. The amount shall be a one-time payment of \$105 per acre of long-term or permanent disturbance (totaling \$185,850.00 for disturbance area of 1,770 acres, to be adjusted according to final project footprint).

Verification: No later than 30 days prior to the start of construction, the project owner shall provide written verification to the CPM that NFWF has received and accepted payment into the project's sub-account of the REAT Account to support the USFWS Regional Raven Management Program.

No later than 30 days prior to any construction-related ground disturbance activities, the Project owner shall provide the CPM, USFWS, and CDFG with the final version of a Raven Management Plan. All modifications to the approved Raven Management Plan shall be made only with approval of the CPM in consultation with Western, BLM, USFWS and CDFG.

Within 30 days after completion of Project construction, the Project owner shall provide to the CPM for review and approval, a written report identifying which items of the Raven Management Plan have been completed, a summary of all modifications to mitigation measures made during the Project's construction phase, and which items are still outstanding.

On January 31st of each year following construction the Designated Biologist shall provide a report to the CPM that includes: a summary of the results of raven management and control activities for the year; a discussion of whether raven control and management goals for the year were met; and recommendations for raven management activities for the upcoming year.

GOLDEN EAGLE PRE-CONSTRUCTION SURVEYS

BIO-18 The Project owner shall implement the following measures to avoid or minimize Project-related construction impacts to golden eagles.

1. Annual Inventory During Construction. For each year during which construction will occur an inventory shall be conducted to determine if golden eagle territories occur within ten miles of the solar generator site and generator tie-line alignment and within two miles of the existing Parker-Blythe #2 transmission line alignment. Survey methods for the inventory shall be as described in the *Interim Golden Eagle Inventory and Monitoring Protocols; and Other Recommendations* (Pagel et al. 2010) or more current guidance from the USFWS.

2. Inventory Data: Data collected during the inventory shall include at least the following: territory status (unknown, vacant, occupied, breeding successful, breeding unsuccessful); nest location, nest elevation; age class of golden eagles observed; nesting chronology; number of young at each visit; digital photographs; and substrate upon which nest is placed.
3. Determination of Unoccupied Territory Status: A nesting territory or inventoried habitat shall be considered unoccupied by golden eagles only after completing at least two full aerial surveys in a single breeding season. In circumstances where ground observation occurs rather than aerial surveys, at least two ground observation periods lasting at least four hours are necessary to designate an inventoried habitat or territory as unoccupied as long as all potential nest sites and alternate nests are visible and monitored. These observation periods shall be at least 30 days apart for an inventory, and at least 30 days apart for monitoring of known territories.
4. Monitoring and Adaptive Management Plan: If an occupied nest (as defined by Pagel et al. 2010) is detected within 10 miles of the solar generator site or generator tie-line alignment, or within two miles the Parker-Blythe #2 transmission line alignment, the Project owner shall prepare and implement a Golden Eagle Monitoring and Management Plan for the duration of construction to ensure that Project construction activities do not result in injury or disturbance to golden eagles. The monitoring methods shall be consistent with those described in the *Interim Golden Eagle Inventory and Monitoring Protocols; and Other Recommendations* (Pagel et al. 2010) or more current guidance from the USFWS. The Monitoring and Management Plan shall be prepared in consultation with the USFWS. Triggers for adaptive management shall include any evidence of Project-related disturbance to nesting golden eagles, including but not limited to: agitation behavior (displacement, avoidance, and defense); increased vigilance behavior at nest sites; changes in foraging and feeding behavior, or nest site abandonment. The Monitoring and Management Plan shall include a description of adaptive management actions, which shall include, but not be limited to, cessation of construction activities that are deemed by the Designated Biologist to be the source of golden eagle disturbance.

Verification: No fewer than 30 days from completion of the golden eagle inventory the Project owner shall submit a report to the CPM, Western, CDFG, BLM, and USFWS documenting the results of the inventory.

If an occupied nest is detected within 10 miles of the solar generator site or generator tie-line alignment, or within two miles of the existing Parker-Blythe #2 transmission line alignment, then at least 30 days prior to the start of any pre-construction site mobilization the project owner shall provide the CPM, Western, BLM, CDFG, and USFWS with the final version of the golden eagle monitoring and management plan. This final plan shall have been reviewed and approved by the CPM, USFWS, and Western in consultation with BLM, and CDFG. If no occupied nests are detected during the inventory and a plan is not warranted, a letter from USFWS documenting this determination shall be submitted to the CPM and Western at least 10 days prior to the start of any pre-construction site mobilization.

BURROWING OWL IMPACT AVOIDANCE, MINIMIZATION, AND COMPENSATION MEASURES

BIO-19 The project owner shall implement the following measures to avoid and offset impacts to burrowing owls. Nothing in this condition requires the project owner to conduct burrowing owl surveys by entering private lands adjacent to the project site when the project owner has made reasonable attempts to obtain permission to enter the property for survey work but was unable to obtain such permission. In this situation only, the project owner may substitute binocular surveys for protocol field surveys.

1. Pre-Construction Surveys. Concurrent with desert tortoise clearance surveys, the Designated Biologist shall conduct pre-construction surveys for burrowing owls no more than 30 days prior to the start of ground disturbing activities in any part of the project area. Surveys shall be conducted within the project site and along all linear facilities in accordance with CDFG guidelines (CBOC 1993). Surveys shall also be completed within 500 feet of all project disturbances.
2. Implement Avoidance Measures. If an active burrowing owl burrow is detected within 500 feet from the Project Disturbance Area the following avoidance and minimization measures shall be implemented:
 - a. Establish Non-Disturbance Buffer. Fencing shall be installed at a 250-foot radius from the occupied burrow to create a non-disturbance buffer around the burrow. The non-disturbance buffer and fence line may be reduced to 160 feet if all Project-related activities that might disturb burrowing owls would be conducted during the non-breeding season (September 1st through January 31st). Signs shall be posted in English and Spanish at the fence line indicating no entry or disturbance is permitted within the fenced buffer.
 - b. Monitoring: If construction activities would occur within 500 feet of the occupied burrow during the nesting season (February 1 – August 31st) the Designated Biologist or Biological Monitor shall monitor to determine if these activities have potential to adversely affect nesting efforts, and shall implement measures to minimize or avoid such disturbance.

3. Passive Relocation of Burrowing Owls. If active burrowing owl burrows are detected within the Project Area, the Project owner shall prepare and implement a Burrowing Owl Relocation and Mitigation Plan, in addition to the avoidance measures described above. The final Burrowing Owl Relocation and Mitigation Plan shall be based on the applicant's draft plan (CH2MHill 2010h) revised to incorporate pending review and recommendations by the CPM in consultation with Western ,USFWS, BLM and CDFG, and shall:
 - a. Identify and describe suitable burrow replacement sites within 1 mile of the Project Disturbance Area, and describe measures to ensure that burrow installation or improvements would not affect sensitive species habitat or any burrowing owls already present in the relocation area; burrow replacement sites shall be in areas of suitable habitat for burrowing owl nesting, and be characterized by minimal human disturbance and access. Relative cover of non-native plants within the proposed relocation sites shall not exceed the relative cover of non-native plants in the adjacent habitats;
 - b. Provide guidelines for creation or enhancement of at least two natural or artificial burrows for each active burrow within the project disturbance area, including a discussion of timing of burrow improvements, specific location of burrow installation, and burrow design. Design of the artificial burrows shall be consistent with CDFG guidelines (CDFG 1995) and shall be approved by the CPM in consultation with Western, CDFG, BLM and USFWS; if artificial burrows are required, they shall be located on applicant-owned lands outside of the project boundary where construction/ development would not occur, and at sufficient distance from the project site to minimize noise and other disturbance;
 - c. Provide detailed methods and guidance for passive relocation of burrowing owls occurring during non-breeding season within the Project Disturbance Area. Occupied burrows may not be disturbed during the nesting season (February 1 to August 31) to avoid "take" under the MBTA and Fish and Game codes; and
 - d. Describe monitoring and management of the replacement burrow site(s), and provide a reporting plan. The objective shall be to manage the relocation area for the benefit of burrowing owls, with the specific goals of:
 - i. maintaining the functionality of the burrows for a minimum of two years; and
 - ii. Minimizing the occurrence of weeds (species considered "moderate" or "high" threat to California wildlands as defined by CAL-IPC [2006] and noxious weeds rated "A" or "B" by the California Department of Food and Agriculture and any federal-

rated pest plants [CDFA 2009]) at less than 10 percent cover of the shrub and herb layers.

4. Surveys of Relocation Area. The Designated Biologist shall survey the relocation area(s) containing the artificial burrows installed in accordance with Item 3 above during the nesting and wintering seasons to assess use of the artificial burrows, using methods consistent with Phase II and Phase III California Burrowing Owl Consortium Guideline protocols (CBOC 1993). Surveys shall start upon completion of artificial burrow construction and shall continue for a period of five years. If survey results indicate burrowing owls are not using the relocation area, remedial actions shall be developed and implemented in consultation with the CPM, Western, BLM, CDFG, and USFWS to correct conditions at the site that might be preventing owls from using it. A report describing survey results and remedial actions taken shall be submitted to the CPM, Western, BLM, CDFG, and USFWS no later than January 31st of each year for five years.
5. Acquisition and protection of compensatory mitigation lands for burrowing owls. The Project owner shall provide, in fee or in easement, for the management and protection in perpetuity of 19.5 acres of land for each single burrowing owl or breeding pair or burrowing owls that is displaced by construction of the Project. This compensation acreage of 19.5 acres per single bird or pair of nesting owls assumes that there is no evidence that the compensation lands are occupied by burrowing owls. If burrowing owls are observed to occupy the compensation lands, then only 9.75 acres per single bird or pair is required, per CDFG (1995) guidelines. If the compensation lands are contiguous to currently occupied habitat, then the replacement ratio will be 13.0 acres per pair or single bird.

Compensation land acreage and cost estimates described here are based on the applicant's report that as many as five single burrowing owls or breeding pairs may occur on the solar generator site and one or two single owls or breeding pairs may occur along the generator tie-line alignment. No estimates of burrowing owl numbers on the 161-kV Parker-Blythe transmission line are available. At 19.5 acres of compensation land per single owl or nesting pair, the project owner shall be responsible for dedicating and protecting 136.5 acres of burrowing owl habitat. This estimated acreage shall be adjusted based upon pre-construction survey data and the occurrence of burrowing owls on proposed compensation lands (above).

The project owner shall transfer fee title or a conservation easement on the compensation lands to CDFG under terms approved by CDFG. Alternatively, a non-profit organization qualified to manage compensation lands (pursuant to California Government Code section 65965) and approved by CDFG and the CPM may hold fee title or a conservation easement over the habitat mitigation lands. If the approved non-profit organization holds title, a conservation easement shall be recorded in favor of CDFG in a form approved by CDFG. If the approved non-profit

holds a conservation easement, CDFG shall be named a third party beneficiary. If a Security is provided, the project owner or an approved third party shall complete the proposed compensation lands acquisition within 18 months of the start of project ground-disturbing activities. Acquisition funding shall be based on the adjusted land values at the time of construction. In lieu of acquiring lands itself, the Project owner may satisfy the requirements of this condition by depositing funds into the Renewable Energy Action Team (REAT) Account established with the National Fish and Wildlife Foundation (NFWF), as described in Section 3.i. of Condition of Certification **BIO-16**.

In addition, the Project owner shall provide funding for the enhancement and long-term management of these compensation lands. The acquisition or easement and subsequent management of the compensation lands may be delegated by written agreement to CDFG or to a third party, such as a non-governmental organization dedicated to habitat conservation, subject to approval by the CPM, in consultation with CDFG, Western, BLM, and USFWS prior to land acquisition or management activities. Management funding shall be based on the adjusted transaction and management expenses at the time of construction to acquire and manage habitat.

- a. Criteria for Burrowing Owl Compensation Lands. The terms and conditions of this acquisition or easement shall be as described in Paragraph 1 of **BIO-16** (Desert Tortoise Compensatory Mitigation), with the additional criteria to include: 1) the burrowing owl compensation land must provide suitable habitat for burrowing owls, and 2) the compensation lands must either currently support burrowing owls or be within dispersal distance from areas occupied by burrowing owls (generally approximately 5 miles). The burrowing owl compensation lands may be included with the desert tortoise compensation lands only if these two burrowing owl criteria are met. If the burrowing owl compensation land is separate from the acquisition required for desert tortoise compensation lands, the Project owner shall fulfill the requirements described below in this condition.
- b. Security. If the burrowing owl habitat compensation land is separate from the acreage required for desert tortoise compensation lands, then the Project owner or an approved third party shall complete acquisition of the proposed compensation lands prior to initiating ground-disturbing Project activities. Alternatively, financial assurance can be provided by the Project owner to the CPM with copies of the document(s) to Western, CDFG, BLM and the USFWS, to guarantee that an adequate level of funding is available to implement the mitigation measure described in this condition. These funds shall be used solely for implementation of the measures associated with the Project. Financial assurance can be provided to the CPM in the form of an irrevocable letter of credit, a pledged savings account or another form of security ("Security") prior to initiating ground-disturbing Project

activities. Prior to submittal to the CPM, the Security shall be approved by the CPM, in consultation with Western, CDFG, BLM and the USFWS to ensure funding. As of the publication of the SA/DEIS, this amount is \$358,701.17 but this amount may change based on land costs or adjustments to the estimated costs of enhancement and endowment (see **Biological Resources Table 6** and Compensatory Mitigation Land Security in **BIO-16** for a discussion of the assumptions used in calculating the Security, which are based on an estimate of \$2,622 per acre to fund acquisition, enhancement, and long-term management). The final amount due will be determined by the PAR or PAR-like analysis conducted pursuant to **BIO-16**.

Verification: If pre-construction surveys detect burrowing owls or active burrows outside the project disturbance area but within 500 feet of proposed construction activities, the Designated Biologist shall provide to the CPM, CDFG, USFWS, BLM, and Western a Burrowing Owl Monitoring and Mitigation Plan at least 10 days prior to the start of any project-related site disturbance activities. The project owner shall report monthly to the CPM, CDFG, USFWS, BLM, and Western for the duration of construction on the implementation of burrowing owl avoidance and minimization measures described in the Burrowing Owl Monitoring and Mitigation Plan. Within 30 days after completion of construction the project owner shall provide to the CPM, CDFG, USFWS, BLM, and Western a written construction termination report identifying how mitigation measures described in the plan have been completed.

If pre-construction surveys detect burrowing owls within 500 feet of proposed construction activities, the Designated Biologist shall provide to the CPM, Western, BLM, CDFG and USFWS documentation indicating that non-disturbance buffer fencing has been installed at least 10 days prior to the start of any construction-related ground disturbance activities. The Project owner shall report monthly to the CPM, Western, CDFG, BLM and USFWS for the duration of construction on the implementation of burrowing owl avoidance and minimization measures. Within 30 days after completion of construction the Project owner shall provide to the CPM, Western, BLM, CDFG and USFWS a written construction termination report identifying how mitigation measures described in the plan have been completed.

If pre-construction surveys detect burrowing owls within the Project Disturbance Area, the Project owner shall notify the CPM, Western, BLM, CDFG and USFWS no less than 10 days of completing the surveys that a relocation of owls is necessary. The Project owner shall do all of the following if relocation of one or more burrowing owls is required:

- a. Within 30 days of completion of the burrowing owl pre-construction surveys, submit to the CPM, Western, CDFG and USFWS a Draft Burrowing Owl Relocation and Mitigation Plan.
- b. No less than 90 days prior to purchase or dedication of the burrowing owl compensation lands, the Project owner, or an approved third party, shall submit a formal acquisition proposal to the CPM, Western, CDFG, and USFWS describing the parcel intended for purchase or dedication. At the same time the Project owner shall

submit a PAR or PAR-like analysis for the parcels for review and approval by the CPM, CDFG and USFWS.

- c. Within 90 days of the purchase or dedication, as determined by the date on the title, the Project owner shall provide the CPM with a management plan for review and approval, in consultation with Western, CDFG, BLM and USFWS, for the compensation lands and associated funds.
- d. No later than 30 days prior to the start of construction-related ground disturbing activities, the Project owner shall provide written verification of Security in accordance with this condition of certification.
- e. No later than 18 months after the start of construction-related ground disturbance activities, the Project owner shall provide written verification to the CPM, Western, BLM, CDFG and USFWS that the compensation lands or conservation easements have been acquired and recorded in favor of the approved recipient.
- f. On January 31st of each year following construction for a period of five years, the Designated Biologist shall provide a report to the CPM, USFWS, BLM and CDFG that describes the results of monitoring and management of the replacement burrow area. The annual report shall provide an assessment of the status of the replacement burrow area with respect to burrow function and weed infestation, and shall include recommendations for actions the following year for maintaining the burrows as functional burrowing owl nesting sites and minimizing the occurrence of weeds.

AMERICAN BADGER AND DESERT KIT FOX IMPACT AVOIDANCE AND MINIMIZATION MEASURES

BIO-20 Prior to ground disturbance the project owner shall conduct pre-construction surveys for American badgers and desert kit fox. These surveys may be conducted concurrently with the desert tortoise pre-construction surveys (Condition of Certification **BIO-14**, above). Surveys shall be conducted as described below:

1. Biological Monitors shall perform pre-construction surveys for badger and kit fox dens throughout the project area, including areas within 250 feet of all project facilities, utility corridors, and access roads. If dens are detected, each den shall be classified as inactive, potentially active, or definitely active.
2. Inactive dens within the proposed security and perimeter fences, or that would be directly impacted by any construction activities, shall be excavated by hand and backfilled to prevent reuse by badgers or kit fox. Potentially active dens that would be directly impacted by construction activities shall be monitored by the Biological Monitor for three consecutive nights using a tracking medium (such as diatomaceous earth or fire clay) and/or infrared camera stations at the entrance. If no tracks are observed in the tracking medium or no photos of the target species

are captured after three nights, the den shall be excavated and backfilled by hand.

3. If present, occupied badger or kit fox dens shall be flagged; monitored daily to determine whether the den is occupied by a female with young (i.e., a maternity den) and ground-disturbing activities avoided within 100 feet of the den as long as it remains occupied. Maternity dens shall be avoided during the pup-rearing season (15 February through 1 July) and a minimum 200-foot disturbance-free buffer established. Buffers may be modified with the concurrence of CDFG and the CPM. Maternity dens shall be flagged for avoidance, identified on construction maps, and a biological monitor shall be present during any construction activity within 500 feet of the maternity den.
4. If avoidance of an occupied non-maternity den is not feasible, badgers or kit foxes shall be passively relocated by slowly excavating the burrow (either by hand or mechanized equipment under the direct supervision of the biologist, removing no more than 4 inches at a time) and allowing the animal to disperse from the site (e.g., by providing a temporary monitored opening in the tortoise exclusion fence and directing the animal toward the opening with temporary plastic construction fencing). Female kit foxes or badgers with young would not be directed off-site until the young are ready to leave the dens. Any forced dispersal of badgers or kit foxes shall occur only after consultation with the CDFG and approval by the CPM. A written report documenting the animal's removal or forced dispersal shall be provided to the CPM within 30 days of relocation. In the event that passive relocation techniques fail for badgers, the Applicant will contact CDFG to explore other relocation options, which may include trapping.

Verification: The project owner shall submit a report to the CPM and CDFG within 30 days of completion of badger and kit fox surveys. The report shall describe survey methods, results, further mitigation measures (if any) to be implemented, and shall specify reporting and verification requirements (e.g., CDFG approval for forced dispersal plans) for those measures. Results of any follow-up measures shall be reported to the CPM in monthly and annual compliance reports and on any reporting schedule required or recommended by CDFG.

FENCE LOCATIONS: LOGISTICS, LAY-DOWN AREA, AND ACCESS ROAD

BIO-21 To allow east-west wildlife passage alongside the highway and to minimize road mortality during project construction, the project owner shall design and build the facility to provide a minimum 100-foot unfenced wildlife passage area south of SR-62 and north of the solar field and any contiguous project components that would interrupt wildlife passage. These include temporary and permanent project components, including but not limited to logistics and lay-down areas, administrative area, cultural resources interpretive site, permanent or temporary fencing, security gate, and any other project component, excluding unfenced linear facilities such as access roads or electrical distribution lines. With the exception of minimal disturbance

necessary for linear project features, this wildlife passage area shall consist of undisturbed or revegetated desert shrubland. .

Verification: The project owner shall submit final plan drawings to the CPM and Western no less than 30 days prior to scheduled commencement of ground-disturbing activities, to indicate the location of the wildlife passage area. No fence construction or other ground-disturbing activities shall proceed within the designated wildlife passage area without written authorization of the CPM.

STREAMBED IMPACT MINIMIZATION AND COMPENSATION MEASURES

- BIO-22** The project owner shall implement the following measures to avoid, minimize and mitigate for direct and indirect impacts to waters of the State and to satisfy requirements of California Fish and Game Code sections 1600 and 1607.
1. Eliminate Proposed Storm Water Detention Basins: The project owner shall eliminate the proposed detention basins from the project design. The owner shall design and construct the perimeter road at existing grade in the southern portion of the project site to allow runoff to cross the road freely, as shown in the applicant's Response to CEC Staff Workshop Query 12 (SR 2010a). The project owner may adopt the road design as submitted (SR 2010a) or provide an alternate design to minimize potential for road damage during heavy rains (e.g., the owner may elect to pave the road or install periodic low-water crossings that would not impede runoff).
 2. Finalize Acreages of Impacts to State Waters: Staff estimates that 82.8 acres of state-jurisdictional waters would be directly or indirectly impacted by the project (excluding impacts during construction of the OHGW on the existing Western Parker-Blythe 161 kV transmission line). Upon completion of final engineering, the project owner shall review and quantify the project's permanent and long-term impacts to state-jurisdictional waters. The calculated acreage of permanent and long-term impacts shall include all ephemeral drainages impacted by construction within or adjacent to the fenced boundary of the solar field site, including the proposed logistics and lay-down areas and diversion channels, as well as impacts to drainages resulting from the construction or widening of access for new or existing transmission line access road; transmission line tower access; logistics, staging, and lay-down areas; road turnouts; pull sites; interconnection substation; and any other project-related disturbance to jurisdictional waters.
 3. Acquire Off-Site State Waters: Permanent and long-term impacts to waters of the State shall be mitigated by compensation at a 1:1 ratio. The project owner shall acquire, in fee or in easement, a parcel or parcels of land that includes at least the same acreage of State jurisdictional waters as would be impacted by construction of the project, as determined in Item 1 above. The parcel or parcels comprising the off-site State waters shall include similar vegetation and habitat types as those mapped in the project footprint. The terms and conditions of this acquisition or easement

shall be as described in Condition of Certification **BIO-16**. Mitigation for impacts to State waters shall occur within the surrounding watersheds, as close to the project site as possible. State waters occurring on desert tortoise compensation lands (Condition of Certification **BIO-16**) may be used to fulfill the requirements of this condition. Additional off-site State waters shall be acquired if desert tortoise compensation lands do not contain the minimum acreage of State waters as required for compliance with this Condition of Certification.

4. Preparation and Implementation of Habitat Management Plan for Off-site Compensation Land: The project owner shall prepare and implement a Management Plan that describes site-specific enhancement measures for the acquired compensation lands, as described in Condition of Certification **BIO-16**. The Management Plan, as developed for Condition of Certification **BIO-16**, shall include site-specific enhancement measures for all drainages on compensation lands that will be used to fulfill the requirements of this Condition of Certification. Any additional lands beyond those required for compliance with Condition of Certification **BIO-16** that may be required for compliance with this Condition of Certification shall also be included in the Management Plan. The management plan shall be submitted for the CPM'S review in consultation with CDFG, Western, and BLM.
5. Code of Regulations: The project owner shall provide a copy of the Streambed Impact Minimization and Compensation Measures from the Energy Commission Decision and Western and BLM Records of Decision to all contractors, subcontractors, and the project owner's project supervisors. Copies shall be readily available at work sites at all times during periods of active work and must be presented to any CDFG personnel or personnel from another agency upon demand. The CPM reserves the right to issue a stop work order or allow CDFG to issue a stop work order after giving notice to the project owner and the CPM, if the CPM in consultation with CDFG determines that the project owner has breached any of the terms or conditions or for other reasons, including but not limited to the following:
 - a. The information provided by the project owner regarding streambed alteration is incomplete or inaccurate;
 - b. New information becomes available that was not known to it in preparing the terms and conditions; or
 - c. The project or project activities as described in future environmental documentation or in decision documents prepared by the Energy Commission, Western or BLM have changed.
6. Best Management Practices: The project owner shall also comply with the following conditions to protect drainages near the Project Disturbance Area:

- a. The project owner shall not operate vehicles or equipment in ponded or flowing water except as described in this condition.
- b. With the exception of the detention basin(s) and drainage control system installed for the project, the installation of bridges, culverts, or other structures shall be such that water flow (velocity and low flow channel width) is not impaired. Bottoms of temporary culverts shall be placed at or below stream channel grade.
- c. When any activity requires moving of equipment across a flowing drainage, such operations shall be conducted without substantially increasing stream turbidity.
- d. Vehicles driven across ephemeral drainages when water is present shall be completely clean of petroleum residue and water levels shall be below the vehicles' axles.
- e. The project owner shall minimize road building, construction activities, and vegetation clearing within ephemeral drainages to the extent feasible for all project components both within and outside the perimeter fence.
- f. The project owner shall not allow water containing mud, silt, or other pollutants from grading, aggregate washing, or other activities to enter off-site state-jurisdictional waters or be placed in locations that may be subjected to high storm flows.
- g. The project owner shall comply with all litter and pollution laws. All contractors, subcontractors, and employees shall also obey these laws, and it shall be the responsibility of the project owner to ensure compliance.
- h. Spoil sites shall be located and protected as necessary to prevent spoils from eroding into any off-site state-jurisdictional waters. No spoils shall be placed in locations that may be subjected to high storm flows, where spoils might be washed back into drainages.
- i. Raw cement/concrete or washings thereof, asphalt, paint or other coating material, oil or other petroleum products, or any other substances that could be hazardous to vegetation or wildlife resources, resulting from project-related activities, shall be prevented from contaminating the soil and/or entering off-site state-jurisdictional waters. These materials, placed within or where they may enter a drainage by the project owner or any party working under contract or with the permission of the project owner, shall be removed immediately.
- j. No broken concrete, debris, soil, silt, sand, bark, slash, sawdust, rubbish, cement or concrete or washings thereof, oil or petroleum products or other organic or earthen material from any construction or

associated activity of whatever nature shall be allowed to enter into, or placed where it may be washed by rainfall or runoff into, off-site state-jurisdictional waters .

- k. When operations are completed, any excess materials or debris shall be removed from the work area. No rubbish shall be deposited within 150 feet of the high water mark of any category 3, 4, or 5 streambed or any streambed greater than 10 feet wide.
 - l. No equipment maintenance shall occur within 150 feet of any category 3, 4, or 5 streambed or any streambed greater than 10 feet wide and no petroleum products or other pollutants from the equipment shall be allowed to enter these areas or enter any off-site state-jurisdictional waters under any flow.
 - m. Stationary equipment such as motors, pumps, generators, and welders, located within or adjacent to a drainage, shall be positioned over drip pans. Stationary heavy equipment shall have suitable containment to handle a catastrophic spill/leak. Clean up equipment such as booms, absorbent pads, and skimmers shall be on site prior to the start of construction.
 - n. The cleanup of all spills shall begin immediately. The CPM, Western, CDFG, and BLM shall be notified immediately by the project owner of any spills and shall be consulted regarding clean-up procedures.
7. Non-Native Vegetation Removal. The project owner shall remove any non-native vegetation (Consistent with the Weed Management Plan, Condition of Certification **BIO-11**) from any drainage on the project site that requires the placement of a bridge, culvert, or other structure. Removal shall be done at least twice annually (Spring/Summer) throughout the life of the project.
8. Reporting of Special-Status Species: Consistent with Condition of Certification **BIO-2**, if any special-status species are observed on or in proximity to the project site, or during project surveys, the project owner shall submit California Natural Diversity Data Base (CNDDDB) forms and maps to the CNDDDB within five working days of the sightings and provide the regional CDFG office with copies of the CNDDDB forms and survey maps. The CNDDDB form is available online at: www.dfg.ca.gov/whdab/pdfs/natspec.pdf. This information shall be mailed within five days to: California Department of Fish and Game, Natural Diversity Data Base, 1807 13th Street, Suite 202, Sacramento, CA 95814, (916) 324-3812. A copy of this information shall also be mailed within five days to the CPM, Western, USFWS, CDFG, and BLM.
9. Avoidance (North of Desert Center Alternative): If the North of Desert Center Alternative is selected, project design and implementation shall avoid direct or indirect impacts to the primary wash on the site and a 100-

foot buffer area surrounding the wash, including associated native vegetation.

10. **Notification:** The project owner shall notify the CPM, Western, BLM, and CDFG, in writing, at least five days prior to initiation of project activities in jurisdictional areas and at least five days prior to completion of project activities in jurisdictional areas. The project owner shall notify the CPM, Western, BLM, and CDFG of any change of conditions to the project, the jurisdictional impacts, or the mitigation efforts, if the conditions at the site of the proposed project change in a manner which changes risk to biological resources that may be substantially adversely affected by the proposed project. The notifying report shall be provided to the CPM, Western, BLM, and CDFG no later than 7 days after the change of conditions is identified. As used here, change of condition refers to the process, procedures, and methods of operation of a project; the biological and physical characteristics of a project area; or the laws or regulations pertinent to the project, as described below. A copy of the notifying change of conditions report shall be included in the annual reports.
- a. **Biological Conditions:** a change in biological conditions includes, but is not limited to, the following: 1) the presence of biological resources within or adjacent to the project area, whether native or non-native, not previously known to occur in the area; or 2) the presence of biological resources within or adjacent to the project area, the status of which has changed to endangered, rare, or threatened, as defined in section 15380 of Title 14 of the California Code of Regulations.
 - b. **Physical Conditions:** a change in physical conditions includes, but is not limited to, the following: 1) a change in the morphology of a river, stream, or lake, such as the lowering of a bed or scouring of a bank, or changes in stream form and configuration caused by storm events; 2) the movement of a river or stream channel to a different location; 3) a reduction of or other change in vegetation on the bed, channel, or bank of a drainage, or 4) changes to the hydrologic regime such as fluctuations in the timing or volume of water flows in a river or stream.
 - c. **Legal Conditions:** a change in legal conditions includes, but is not limited to, a change in Regulations, Statutory Law, a Judicial or Court decision, or the listing of a species, the status of which has changed to endangered, rare, or threatened, as defined in section 15380 of Title 14 of the California Code of Regulations.

Verification: Within 30 days of the completion of final engineering, the project owner shall notify the CPM, Western, BLM, and CDFG of the total acreage of impacts to jurisdictional waters. No fewer than 30 days prior to the start of any site or related facilities mobilization activities, the project owner shall implement the construction-related mitigation measures described above, shall verify that appropriate compensation lands have been identified, and shall submit a draft Habitat Management Plan for the identified compensation lands. No fewer than 30 days prior to the start of work potentially affecting waters of the State, the project owner shall provide written

verification (i.e., through incorporation into the BRMIMP) to the CPM, Western, BLM, and CDFG that the above best management practices will be implemented and provide a discussion of planned work in waters of the State in Compliance Reports for the duration of the project.

Within 30 days after completion of the first year of project construction, the project owner shall provide to the CPM, Western, BLM, and CDFG for review and approval a report identifying that appropriate compensatory mitigation lands have been obtained, that the Habitat Management Plan has been reviewed and approved by all responsible agencies, that implementation as specified in the Plan has been initiated, verification of ongoing enhancement techniques, and a summary of all modifications made to the existing channels.

Verification of non-native vegetation removal from drainages on-site, and reporting of special-status species shall be included in monthly and annual compliance reports (Condition of Certification **BIO-2**). Verification of implementation and completion of the compensation land Habitat Management Plan shall be as specified in that Plan.

COUCH'S SPADEFOOT SURVEYS AND BREEDING HABITAT AVOIDANCE

BIO-23 The Project Owner shall implement focused surveys to delineate any potential Couch's spadefoot breeding habitat along the lengths of the generator tie-line alignment and the existing 161-kV Parker-Blythe #2 transmission line alignment and delineate these areas for avoidance in consultation with Western, CDFG, and BLM. These surveys shall be conducted prior to the initiation of ground disturbance for transmission line construction work and shall be conducted by a biologist knowledgeable with Couch's spadefoot biology and habitat. No disturbance shall take place within suitable breeding ponds while water is present. If suitable breeding ponds, adult spadefoots, eggs, or larvae/tadpoles are found, a 200 foot buffer shall be placed around these areas and shall remain in place until the larva/tadpoles complete metamorphosis and retreat to upland areas or until the pools are completely dry.

Impacts to all potential breeding habitat for Couch's spadefoot shall be avoided to the extent feasible. If work within this habitat cannot be avoided, work shall be conducted only while any potential breeding pools are completely dry.

Verification: No less than 30 days prior to initiating ground disturbing activities along either transmission line alignment, the project biologist shall provide a written report detailing the survey results and compliance with avoidance measures to the CPM for review in consultation with Western, CDFG, and BLM.

EVAPORATION POND DESIGN, MONITORING, AND MANAGEMENT PLAN

BIO-24 The project owner shall cover the evaporation ponds prior to any discharge with 1.5-inch mesh netting designed to exclude birds and other wildlife from drinking or landing on the water of the ponds. Netting with mesh sizes other

than 1.5-inches may be installed if approved by the CPM in consultation with CDFG and USFWS. The netted ponds shall be monitored regularly to verify that the netting remains intact, is fulfilling its function in excluding birds and other wildlife from the ponds, and does not pose an entanglement threat to birds and other wildlife. The ponds shall include a visual deterrent in addition to the netting, and shall be designed such that the netting shall never contact the water.

The project owner shall also design and implement an Evaporation Pond Design, Monitoring, and Management Plan (Evaporation Pond Plan) that meets the approval of the CPM, USFWS, CDFG, and Western. The goal of the Evaporation Pond Plan shall be to avoid the potential for bird and wildlife mortality associated with the evaporation ponds. The Evaporation Pond Plan shall include:

1. A discussion of the objectives of the Evaporation Pond Plan;
2. A description of project design features such as side slope specifications, freeboard and depth requirements, covering, and fencing;
3. A discussion on the placement of the evaporation ponds as to reduce the potential of collision or electrocution of wildlife near the transmission line;
4. Monitoring of the ponds, which shall include:
 - a. Monthly Monitoring. The Designated Biologist or Biological Monitor shall regularly survey the ponds at least once per month starting with the first month of operation of the evaporation ponds. The purpose of the surveys shall be to determine if the netted ponds are effective in excluding birds, if the nets pose an entrapment hazard to birds and wildlife, and to assess the structural integrity of the nets. Surveys shall be of sufficient duration and intensity to provide an accurate assessment of bird and wildlife use of the ponds during all seasons. Surveyors shall be experienced with bird identification and survey techniques. Operations staff at the project site shall also report finding any dead birds or other wildlife at the evaporation ponds to the Designated Biologist within one day of the detection of the carcass. The Designated Biologists shall report any bird or other wildlife deaths or entanglements within two days of the discovery to the CPM, Western, CDFG, and USFWS.
 - b. Dead or Entangled Birds. If dead or entangled birds are detected, the Designated Biologist shall take immediate action to correct the source of mortality or entanglement. The Designated Biologist shall make immediate efforts to contact and consult the CPM, Western, CDFG, and USFWS by phone and electronic communications prior to taking remedial action upon detection of the problem, but the inability to reach these parties shall not delay taking action that would, in the judgment of the Designated Biologist, prevent further mortality of birds or other wildlife at the evaporation ponds.

- c. Quarterly Monitoring. If after 12 consecutive monthly site visits no bird or wildlife deaths or entanglements are detected by or reported to the Designated Biologist, monitoring can be reduced to quarterly visits.
 - d. Biannual Monitoring. If after 12 consecutive quarterly site visits no bird or wildlife deaths or entanglements are detected by or reported to the Designated Biologist, and with approval from the CPM, USFWS and CDFG, future surveys may be reduced to two surveys per year, during spring and fall migration.
5. Management actions such as bird deterrence/hazing and water level management and triggers for those management actions; and
 6. Reporting requirements.

Verification: No less than 30 days prior to operation of the evaporation ponds the project owner shall provide to the CPM as-built drawings and photographs of the ponds indicating that the bird exclusion netting has been installed. At least 30 days prior to start of any project-related ground disturbance activities, the project owner shall provide the CPM, Western, USFWS, and CDFG with the final version of the Evaporation Pond Plan that has been reviewed and approved by USFWS, CDFG, and staff. The CPM shall determine the plan's acceptability within 15 days of receipt of the final plan. All modifications to the approved Evaporation Pond Plan must be made only after consultation with the CPM, Western, USFWS, and CDFG. The project owner shall notify the CPM no less than 5 working days before implementing any CPM-approved modifications to the Evaporation Pond Plan.

Within 30 days after completion of project construction, the project owner shall provide to the CPM for review and approval a report identifying which items of the Evaporation Pond Plan have been completed, a summary of all modifications to mitigation measures made during the project's construction phase, and as-built drawings of the evaporation ponds.

For the first year of operation the Designated Biologist shall submit quarterly reports to the CPM, Western, CDFG, and USFWS describing the dates, durations and results of site visits conducted at the evaporation ponds. Thereafter the Designated Biologist shall submit annual monitoring reports with this information. The quarterly and annual reports shall fully describe any bird or wildlife mortality or entanglements detected during the site visits or at any other time, and shall describe actions taken to remedy these problems. The annual report shall be submitted to the CPM, Western, CDFG, and USFWS no later than January 31st of every year for the life of the project.

AVIAN AND BAT PROTECTION PLAN / MONITORING OPERATIONAL IMPACTS OF SOLAR COLLECTION FACILITY ON BIRDS AND BATS

BIO-25 Avian and Bat Protection Plan: The project owner shall prepare and implement an Avian and Bat Protection Plan adopting all applicable guidelines recommended by the USFWS (2010e) in coordination with the Heliostat Positioning Plan (Condition of Certification **TRANS-5**) to minimize death and injury of birds or bats from (1) collisions with facility features

including the heliostat structures, central tower, and generator tie-line towers or transmission lines and (2) focused light and heat at and near the central tower or at “standby points” while the heliostats are focused away from the tower. The Avian and Bat Protection Plan shall include modifications to proposed plant operation to avoid or minimize focusing heliostats at standby points and, instead, move heliostats into a stowed position or another alternative configuration when the power plant is in standby mode. The Avian and Bat Protection Plan shall identify additional adaptive management measures to minimize collisions and incinerations. The Avian and Bat Protection Plan shall also provide documentation that the project is in compliance with the Bald and Golden Eagle Protection Act (Title 16, United States Code, Section 668) and shall provide specific construction activity and scheduling guidelines for installation of the overhead fiber-optic ground wire along Western’s existing 161-kV Parker-Blythe #2 transmission line to avoid disturbance to golden eagle nesting territories. The Avian and Bat Protection Plan shall provide a reporting schedule for all actions taken during project construction or operation. Upon USFWS approval, it shall be reviewed and approved by the CPM in consultation with Western, CDFG, and BLM. Upon review and approval, it shall be incorporated into the project’s BRMIMP and implemented.

Bird and Bat Monitoring Study: The project owner shall prepare and implement a Bird and Bat Monitoring Study to monitor the death and injury of birds and bats from collisions with project facilities including heliostats and solar receiver tower, and burning caused by flying through focused sunlight around the solar receiver tower or standby points. The study design shall be approved by the CPM in consultation with Western, CDFG and USFWS, and shall be incorporated into the project’s BRMIMP and implemented by the Designated Biologist in coordination with the project owner, CPM, Western, CDFG, BLM, and USFWS. The Bird and Bat Monitoring Study shall include detailed specifications on data and carcass collection protocol, to include identification of each carcass to species wherever possible and a proposed schedule of carcass searches to be based upon a valid sampling rationale. All bird or bat carcasses shall be retained in a freezer on-site, with all collection data written on an attached data form, pending disposition to CDFG or a certified museum (e.g., San Bernardino County Museum; Western Foundation of Vertebrate Zoology or California Academy of Sciences) pending recommendation of the wildlife agencies. For any special-status species carcasses, the Biological Monitor shall contact CDFG and USFWS (for golden eagle or any federally-listed species) within one working day of receipt of the carcass for guidance on disposal or storage of the carcass. The Biological Monitor shall report the special-status species record as described in Conditions of Certification **BIO-2**, **BIO-7**, and **BIO-22**.

The study shall also include seasonal trials to assess bias from carcass removal by scavengers as well as searcher bias.

Adaptive management and mitigation strategies that may be implemented in the event that the Bird and Bat Monitoring Study identifies the need for

additional mitigation could include the use of visual or auditory deterrents, or the acquisition and conservation of offsite habitat of similar type and quality as was present at the RSEP site prior to project development.

Verification: No more than 60 days following the docketing of the Energy Commission Final Decision or publication of Western's Record of Decision, whichever comes first, the project owner shall submit for approval by the CPM, in consultation with Western, BLM, and CDFG a final Avian and Bat Protection Plan which has already been reviewed and approved by USFWS. The Plan shall include documentation that the project is in compliance with the Bald and Golden Eagle Protection Act (Title 16, United States Code Section 668). This documentation shall include a written or electronic transmittal from the USFWS indicating its approval of the Avian and Bat Protection Plan, the status of any permit that may be required, and any follow-up actions required by the applicant. Modifications to the Avian and Bat Protection Plan shall be made only after approval from the CPM, in consultation with Western, BLM, USFWS, and CDFG.

Implementation and results of the Avian and Bat Protection Plan shall be described in periodic reports, scheduled according to the reporting schedule set forth in the approved Plan. The project owner shall submit reports to the CPM for review and approval, in consultation with Western, CDFG, BLM, and USFWS.

No more than 30 days following the publication of the Energy Commission Decision, the project owner shall submit to the CPM, Western, USFWS, and CDFG a draft Bird and Bat Monitoring Study. At least 60 days prior to start of any project-related ground disturbance activities, the project owner shall provide the CPM with the final version of the Bird and Bat Monitoring Study, as reviewed and approved by the CPM in consultation with Western, CDFG and USFWS. Modifications to the Bird and Bat Monitoring Study shall be made only with the approval of the CPM in consultation with Western, CDFG and USFWS.

For at least two years following the beginning of operation the project owner shall submit quarterly reports to the CPM, Western, CDFG, and USFWS describing the dates, durations, and results of monitoring. The quarterly reports shall provide detailed descriptions of any project-related bird or wildlife deaths or injuries detected during the monitoring study or at any other time.

Following the completion of the fourth quarter of monitoring each year, the Designated Biologist shall prepare an Annual Report that summarizes the year's data, analyzes any project-related bird and/or bat fatalities or injuries detected, and provides recommendations for future monitoring and any adaptive management actions needed. The Annual Report shall be provided to the CPM, Western, CDFG, and USFWS.

Quarterly reporting shall continue until the CPM, in consultation with Western, CDFG and USFWS, determine whether further monitoring is needed, and whether mitigation (e.g., development and/or implementation of bird deterrent technology, etc.) and/or adaptive management measures are necessary. After the Bird and Bat Monitoring Study is determined by the CPM to be complete, the project owner or contractor shall prepare a paper that describes the study design and monitoring results to be submitted

to a peer-reviewed scientific journal. A copy of the manuscript and proof of submittal shall be provided to the CPM within one year of concluding the monitoring study.

IN-LIEU FEE MITIGATION OPTION

BIO-26 The Project owner may choose to satisfy its mitigation obligations identified in this Decision by paying an in lieu fee instead of acquiring compensation lands, pursuant to Fish and Game code sections 2069 and 2099 or any other applicable in-lieu fee provision, provided that the project's in-lieu fee provision is found by the Commission to be in compliance with CEQA and CESA requirements. If the in-lieu fee proposal is found by the Commission to be in compliance, and the Project Owner chooses to satisfy its mitigation obligations through the in-lieu fee, the Project Owner shall provide proof of the in-lieu fee payment to the CPM.

Verification: If electing to use this provision, the Project Owner shall notify the Commission and all parties to the proceeding that it would like a determination that the Project's in-lieu fee proposal meets CEQA and CESA requirements. If the project owner elects to use this provision prior to posting security required by the conditions of certification, the Project Owner shall provide proof of the in-lieu fee payment to the CPM prior to any ground disturbance. If the Project owner elects to use this provision after posting such security, the Project owner shall provide proof of the in lieu fee payment prior to the time required for habitat compensation lands to be surrendered in accordance with the Condition of Certification.

CONCLUSIONS

With implementation of staff's proposed conditions of certification, construction and operation of the proposed RSEP solar generator, generator tie-line and interconnector substation would comply with all federal, State, and local laws, ordinances, regulations, and standards relating to biological resources. Staff's generally does not reach conclusions with regard to the proposed OPGW on Western's existing 161-kV Parker-Bythe #2 transmission line, pending availability of additional information on biological resources and delineation of state and federally jurisdictional streambeds, on the alignment. For this project component, significance of potential impacts to biological resources and compliance with LORS remain uncertain. The assessment of RSEP's effects to Biological resources associated with the telecommunications option to attach a fiber optic cable on the Parker-Blythe #2 Transmission Line will be updated for the CEC's record and the FEIS when additional information is received from the applicant. A more complete summary of staff's conclusions is provided in the first section of this chapter.

Four of staff's recommended Conditions of Certification would require the Project owner to acquire compensation lands to mitigate the Project's impacts to biological resources. The most significant of these is **BIO-16** (Desert Tortoise Compensatory Mitigation). The others are Conditions of Certification **BIO-12**, **BIO-19**, and **BIO-22**. **BIO-12** (Special-Status Plant Impact Avoidance and Minimization) provides the option of mitigating impacts to rare plants that may be discovered on the site during late-season botanical surveys through habitat compensation. **BIO-19** (Burrowing Owl Impact Avoidance, Minimization, and Compensation Measures) would require compensation for project

impacts to this animal. **BIO-22** (Streambed Impact Minimization and Compensation Measures) would require compensation for jurisdictional streambed acreage impacted by the project. In each of these conditions, staff recommends a financial security to ensure adequate funding to acquire and manage the compensation lands. Staff recommends that this security should be equal to staff's estimated costs for habitat compensation and management. Staff recognizes that some potential compensation lands may support more than one of these resources, and staff recommends that, wherever applicable, the project owner should seek compensation lands meeting selection criteria for more than one of these resources, as described in these Conditions of Certification, below. However, pending acquisition of compensation lands, staff recommends separate securities for each resource.

Staff has calculated the acreage and estimated costs for desert tortoise compensation lands, as described in Condition of Certification **BIO-16**. Staff provides estimates of acreage and costs for burrowing owl compensation in **BIO-19**. Any potential compensation acreage for rare plants, pursuant to **BIO-12**, would be determined upon completion of late-season field surveys and cannot be estimated at this time. Staff anticipates that all compensation lands for state jurisdictional streambeds as required under **BIO-22** would be "nested" within desert tortoise compensation lands, avoiding necessity for additional compensation lands. However, as described in **BIO-22**, further compensation lands may be required dependent upon the extent of state jurisdictional waters on the desert tortoise compensation lands. For streambed compensation, available private land parcels would rarely if ever be made up only of suitable streambed habitat. However, staff bases its estimated cost for compensation of streambed impacts (and recommended security) on the acreage of state-jurisdictional streambed habitat as provided by the applicant. **Biological Resources Table 10**, below, provides staff's cost estimates and recommended security for each of these recommended conditions of certification.

**Biological Resources Table 10
Summary of Compensation Lands Costs¹**

	Desert tortoise compensation	Burrowing owl compensation	Rare plant compensation	Streambed compensation
Number of acres	1988	136.5	Undetermined (pending further surveys)	89
Estimated number of parcels to be acquired, at 160 acres per parcel ²	13	1	n/a	1
Land cost at \$500/acre ³	\$994,000.00	\$68,250.00	n/a	\$44,500.00
Level 1 Environmental Site Assessment at \$3000/parcel	\$39,000.00	\$3,000.00	n/a	\$3,000.00
Appraisal at no less than \$5,000/parcel	\$65,000.00	\$5,000.00	n/a	\$5,000.00
Initial site clean-up, restoration or enhancement, at \$250/acre ⁴	\$497,000.00	\$34,125.00	n/a	\$22,250.00
Closing and Escrow Cost at \$5000/parcel ⁵	\$65,000.00	\$5,000.00	n/a	\$5,000.00
Biological survey for determining mitigation value of land (habitat based with species specific augmentation) at \$20,000/parcel	\$260,000.00	\$20,000.00	n/a	\$20,000.00
3rd Party Administrative Costs (Land Cost x 10%) ⁶	\$99,400.00	\$6,825.00	n/a	\$4,450.00
Agency cost to accept land ⁷ [(Land Cost x 15%) x 1.17] (17% of the 15% for overhead)	\$174,447.00	\$11,977.88	n/a	\$7,809.75
Subtotal - Acquisition and Initial Site Work	\$2,193,847.00	\$154,177.88	n/a	\$112,009.75
Long-term Management and Maintenance Fund (LTMM) fee at \$1450/acre⁸	\$2,882,600.00	\$197,925.00	n/a	\$129,050.00
NFWF Fees				
Establish Project Specific Account	\$12,000.00	n/a	n/a	n/a
Pre-proposal modified RFP or RFP processing ⁹	\$30,000	n/a	n/a	n/a
NFWF Management fee For Acquisition and Enhancement Actions (Subtotal x 3%)	\$65,815.41	\$4,625.34	n/a	\$3,360.30
NFWF Management Fee for LTMM account (LTMM x 1%)	\$28,826.00	\$1,972.95	n/a	\$1,290.50
Subtotal of NFWF Fees	\$136,641.41	\$6,598.29	n/a	\$4,650.80
TOTAL Estimated cost for	\$5,213,088.41	\$358,701.17	n/a	\$245,710.55

deposit in project specific REAT-NFWF Account				
---	--	--	--	--

1. Estimates prepared in consultation with CDFG, USFWS, and BLM. All costs are best estimates as of summer 2010. Actual costs will be determined at the time of the transactions and may change the funding needed to implement the required mitigation obligation. All acreages are staff's estimates based on available data; final acreages to be adjusted.
2. For the purposes of determining costs, a parcel is defined at 40 acres, recognizing that some will be larger and some will be smaller, but that 40 acres provides a good estimate for the number of transactions anticipated (based on input from CDD).
3. Generalized estimate taking into consideration a likely jump in land costs due to demand, and an 18-24 month window to acquire the land after agency decisions are made. If the agencies, developer, or 3rd party has better information on land costs in the specific area where project-specific mitigation lands are likely to be purchased, that data overrides this general estimate. Note: regardless of the estimates, the developer is responsible for providing adequate funding to implement the required mitigation.
4. Based on information from CDFG.
5. Two transactions: landowner to 3rd party; 3rd party to agency.
6. Includes staff time to work with agencies and landowners; develop management plan; oversee land transaction; organizational reporting and due diligence; review of acquisition documents; assembling acquisition acreage, and related tasks)
7. This amount covers the estimate of BLM's cost to accept the land into the public management system and costs associated with tracking/managing the costs associated with the donation acceptance, includes two physical inspections; review and approval of the Level 1 ESA assessment; review of all title documents; drafting deed restrictions; issue escrow instructions; mapping the parcels, and related tasks.
8. Estimate for purposes of calculating general costs. The actual long term management costs will be determined using a PAR (Property Assessment Report) or PAR-like analysis tailored to the specific acquisition. Includes land management; enforcement and defense of easement or title [short and long term]; and monitoring.
9. If determined necessary by the REAT agencies if multiple 3rd parties have expressed interest; for transparency and objective selection of 3rd party to carry out acquisition.

REFERENCES

The tn: 00000 in the references below indicates the transaction number under which the item is catalogued in the Energy Commission's Docket Unit. The transaction number allows for quicker search and retrieval of individual items docketed for a case or used for ease of reference and retrieval of exhibits cited in briefs and used at Evidentiary Hearings.

Cultural Resources

Testimony of Kim J. Tremaine (Energy Commission), Stephen Tromly (Western Area Power Administration), and George Kline (Bureau of Land Management)¹

SUMMARY OF CONCLUSIONS

The U.S. Bureau of Land Management (BLM), Western Area Power Administration (Western) and Energy Commission staff (staff), hereafter jointly referred to as the agencies, have reviewed the Rice Solar Energy Project (RSEP or proposed project) in accordance with the requirements of the National Environmental Policy Act (NEPA) and the California Environmental Quality Act (CEQA).

- Staff² concludes that the proposed Rice Solar Energy Project (RSEP) would have significant direct impacts to the features and artifact concentrations associated with the historic Rice Army Airfield (Rice AAF)³ and the western periphery of Camp Rice (CA-SBA-10526H), as well as potential direct impacts to 23 other eligible or assumed eligible archaeological sites. Implementation of Energy Commission Conditions of Certification **CUL-2** through **CUL-12** would reduce these impacts to a less than significant level under CEQA.
- Staff finds that the RSEP construction impacts, when combined with impacts from the past, present, and reasonably foreseeable projects, contribute in a small but significant way to the cumulatively considerable adverse impacts to cultural resources at the regional level. Implementation of **CUL-1** would reduce that contribution to a less than significant level under CEQA.

Staff recommends adoption of conditions of certification **CUL-1** through **CUL-12**. Implementation of these conditions, as recommended by Energy Commission staff, would satisfy the Energy Commission's responsibility to comply with CEQA, ensure consistency with the applicable LORS, and reduce impacts to cultural resources to a less than significant level. The identification of relevant and reasonable mitigation measures also conforms to NEPA requirements for the BLM/Western analysis that can be considered in the Record of Decision (ROD).

INTRODUCTION

This cultural resources assessment identifies the potential impacts of the Rice Solar Energy Project (RSEP) on cultural resources. Cultural resources are categorized as buildings, sites, structures, objects, and districts under federal law (for the purposes of NEPA and the National Historic Preservation Act (NHPA), Section 106), and under California state law (for the purposes of CEQA). Three kinds of cultural resources, classified by their origins, are considered in this assessment: prehistoric, ethnographic, and historic.

¹ With contributions by Dwight Simons, Beth Bagwell, and Beverly E. Bastian

² "Staff" means Energy Commission staff unless otherwise indicated.

³ No primary number or trinomial has been assigned yet to this resource.

Prehistoric archaeological resources are associated with the human occupation and use of California lands prior to sustained European contact. These resources may include sites and deposits, structures, artifacts, rock art, trails, and other traces of Native American human behavior. Groupings of prehistoric resources are also recognized as archaeological districts and as cultural landscapes. In California, the prehistoric period began over 12,000 years ago and extended through the eighteenth century until 1769, when the first Europeans permanently settled in California.

Ethnographic resources represent the heritage of a particular ethnic or cultural group, such as Native Americans or African, European, Latino, or Asian immigrants. They may include traditional resource-collecting areas, ceremonial sites, value-imbued landscape features, cemeteries, shrines, or ethnic neighborhoods and structures.

Historic-period resources, both archaeological and architectural, are associated with Euro-American exploration and settlement of an area and the beginning of a written historical record. They may include archaeological deposits, sites, structures, traveled ways, artifacts, or other evidence of human activity. Groupings of historic-period resources are also recognized as historic districts and as historic vernacular landscapes. Under both federal and state historic preservation laws, most cultural resources must be at least 50 years old to have sufficient historical importance to merit consideration of eligibility for listing in the NRHP or CRHR. A resource less than 50 years of age must be of exceptional historical importance to be considered for listing.

For the RSEP, staff provides an overview of the environmental setting and history of the project area, an inventory of the cultural resources identified in the project vicinity, an analysis of the project's potential impacts to significant cultural resources, and recommendations of measures by which the project's adverse impacts to significant cultural resources may be avoided or mitigated.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS (LORS)

Projects licensed by the Energy Commission are reviewed to ensure consistency with applicable laws, ordinances, regulations, standards, plans, and policies. **Cultural Resources Table 1** provides a general description of the LORS applicable to the proposed project, all alternatives, and surrounding lands.

CULTURAL RESOURCES Table 1
Applicable Laws, Ordinances, Regulations, and Standards

<u>Applicable LORS</u>	<u>Description</u>
Federal	
Antiquities Act of 1906 16 United States Code (USC) 431–433 National Historic Preservation Act of 1966 (NHPA)	Establishes criminal penalties for unauthorized destruction or appropriation of “any historic or prehistoric ruin or monument, or any object of antiquity” on federal land; empowers the President to establish historical monuments and landmarks. Establishes a process to identify historic properties, determine effect and consultation to reduce, minimize or avoid effects.
Archaeological Resources Protection Act of 1979 (ARPA) 16 USC 470aa et seq.	Protects archaeological resources from vandalism and unauthorized collecting on public and Indian lands.
Native American Graves Protection and Repatriation Act of 1990 (NAGPRA) 25 USC 3001–3013	Provides for the protection of Native American graves, funerary objects, and “objects of cultural patrimony” on federal land; Establishes the procedures for determining ownership for Native American human remains, funerary objects, and other sacred objects under federal jurisdiction.
State	
Public Resources Code (PRC), Section 5097.98(b) and (e)	Requires a landowner on whose property Native American human remains are found to limit further development activity in the vicinity until he/she confers with the Native American Heritage Commission-identified Most Likely Descendants (MLDs) to consider treatment options. In the absence of MLDs or of a treatment acceptable to all parties, the landowner is required to re-inter the remains elsewhere on the property in a location not subject to further disturbance.
PRC, Sections 5097.99 and 5097.991	5097.99 establishes as a felony the acquisition, possession, sale, or dissection with malice or wantonness Native American remains or funerary artifacts. 5097.991 establishes as state policy the repatriation of Native American remains and funerary artifacts.
Health and Safety Code (HSC), Section 7050.5	Makes it a misdemeanor to mutilate, disinter, wantonly disturb, or willfully remove human remains found outside a cemetery; Requires a project owner to halt construction if human remains are discovered and to contact the county coroner.
Local	
Riverside County General Plan, Multipurpose Open Space Element (Chapter 5), Open Space Policies OS 19.2– 19.4	OS 19.2 requires the review of all proposed development for archaeological sensitivity; OS 19.3 Employs procedures to protect the confidentiality and prevent inappropriate public exposure of sensitive archaeological resources when soliciting the assistance of

<u>Applicable LORS</u>	<u>Description</u>
	<p>public and volunteer organizations.</p> <p>OS 19.4 Require a Native American Statement as part of the environmental review process on development projects with identified cultural resources.</p>
<p>Riverside County General Plan, Multipurpose Open Space Element (Chapter 5), Open Space Policies OS 19.5–19.7</p>	<p>OS 19.5 allows the History Division of the Riverside County Regional Park and Open-Space District to evaluate large project proposals for their potential preservation or destruction of historic sites; requires projects to provide feasible mitigation for impacts to historic sites prior to county approval.</p> <p>OS 19.6 enforces the California State Historic Building Code so that historic buildings can be preserved and used without posing a hazard to public safety.</p> <p>OS 19.7 endorses the allocation of resources and/or tax credits to prioritize retrofit of historic structures.</p>
<p>Riverside County General Plan, Exhibit A, CEQA Findings of Fact and Statement of Overriding Considerations, Mitigation Monitoring Program, Measures 4.7.1A, 4.7.1B, and 4.7.1C</p>	<p>Outlines mitigation measures for cultural resources monitoring programs.</p>

Proposed Project (Alternative 1)

SETTING/AFFECTED ENVIRONMENT

Information provided regarding the setting of the proposed project places it in its geographical and geological context and specifies the technical description of the project. Additionally, the prehistoric, ethnographic, and historical background provides the context for the evaluation of the NRHP and CRHR eligibility of any identified cultural resources within staff's area of analysis for this project.

Project Site

The applicant, Rice Solar Energy, LLC (RSE), a subsidiary of Solar Reserve, LLC, is proposing a 150-megawatt (MW) concentrating solar thermal power project with a central receiver tower, sun-tracking heliostat field, and an integral thermal storage for the liquid salt-based system. The power block and solar arrays would cover approximately 1,410 acres of a 2,560-acre project site, immediately south and adjacent to State Route (SR) 62, at milepost 109, approximately 20 miles east of the SR62/177 intersection, and 15 miles west of Vidal Junction, in unincorporated Riverside County. The generating facility would be constructed on privately owned land and connected to the Western Area Power Administration's (Western) Parker-Blythe #2 transmission line by a 10.0-mile-long generation tie-line. The transmission line would be situated primarily on BLM-managed public lands, although it would cross a portion of two privately-owned

parcels. Buildout coverage on the site (final footprint) would be about 55% (1,410 acres), including mirror fields, access roads, and buffer areas outside the fenceline.

From the interconnection substation, telecommunications would be established by: 1) replacing one of two existing overhead ground wires on the Parker-Blythe #2 transmission line with a fiber optic core overhead ground wire to either or both of Western's existing Parker and Blythe substations; 2) microwave (radio-frequency) transmission from either RSEP or the new substation, to terminate at Western's Blythe, Headgate Rock, or Black Point substations, or at an existing telecommunications site at Cunningham Mountain; or 3) by power line carrier/ broadband-over-power-line.

The project would have minimal to moderate ground disturbance impacts on the site area. Within the heliostat field, vegetation would be removed to near ground level and, overall, would retain the existing terrain without any significant grading for placement of the heliostat pylons or piers. The most significant grading would occur in the power block area and for development of the stormwater detention (30 acre-foot capacity) and wastewater evaporation ponds (three ponds at 5 acres each or a total of 15 acres). Trenching for installation of utilities (water, electric, gas, and communication) would occur to a depth of ten feet. Drainage diversion channels would be excavated around the northern half of the perimeter of the project facility, with the perimeter access road acting as a berm to prevent storm water from running onto the RSEP site from upslope areas. Grading and excavation would be necessary for the foundations of the project structures, including the central tower, heliostats, pipe racks, turbine, administration buildings, storage tanks for water and liquid salt, and transmission poles. Estimated foundation depths for the central tower range between 6 and 20 feet, with a diameter of about 115 feet. The donut foundation would have a central depth (immediately beneath the tower) of 20 feet and decreasing to a depth of 8 feet at the outer edges. Foundations for the heliostats would be 10 to 12 feet deep and 33 inches in diameter. Installation of the two project wells would require boring to a depth of about 190 feet.

The project's power block and solar arrays would be located on the site of the Rice AAF and a portion of Camp Rice, a World War II (WWII) desert training base that was part of the infantry and artillery Desert Training Center, California-Arizona Maneuver Area (DTC/C-AMA). It was used by General George S. Patton, Jr., from 1942-1944 to prepare American soldiers for combat in the North African desert. This location, a municipal airfield prior to WWII, reverted to civilian/public airport status again about 1949, then to a private airfield around 1952. Apparently abandoned between 1955-1958, the airport continued to be used sporadically by private pilots until the runways became unsafe. To the east, Camp Rice (Rice Divisional Camp) housed the 5th Armored Division during its training at the CAMA and maintained a large quartermaster depot at that location. The area was also used for Joint Exercise Desert Strike in 1964 (SR2009a). Little remains of Camp Rice or the Rice Army Airfield on the ground, aside a few foundations, concrete pads, and defunct runways. However, the outline of both the airport and Camp Rice can still be easily discerned from the air.

The site is generally flat, with elevations ranging from about 720 feet (220 meters) above sea level (ASL) at the southern boundary to approximately 820 feet (250 meters) ASL in the north, along SR 62. Native plant revegetation is sparse to moderate and interrupted by the remains of the asphalt, gravel, concrete pads, foundations, runways,

and taxiways. A number of small, dry desert washes traverse the project area, but no large ephemeral washes are present. There are no structures on the site, except for a few decaying foundations stemwalls, and no active use. The proposed project site can best be described as extensively disturbed land that has been unused for about 50 years and is gradually reverting to desert.

Surrounding Area

The proposed project site is located in the northeastern portion of unincorporated Riverside County, approximately 15 miles west of Vidal Junction and 3 miles east of the abandoned town of Rice. The San Bernardino County line is just north of SR 62, which is immediately adjacent to the project's northern boundary. Access to the site is along SR62, a two-lane state highway (also known as Aqueduct Road and Twenty-nine Palms Highway) that bounds the project site to the north, and provides a direct route between Vidal Junction, to the east, and Twenty-nine Palms to the west. SR177 intersects SR62 approximately 17 miles west of the project site and connects to Desert Center and Interstate 10 (I-10) to the south. The Colorado River Aqueduct (Aqueduct) parallels SR62 to the north of the project site. The Aqueduct is a 242-mile (389-kilometer) water conveyance operated by the Metropolitan Water District of Southern California (MWD). The Arizona and California Railroad (ARZC) shortline also parallels SR62 at the project site and extends nearly 300 miles between Matthie, Arizona and Cadiz, California, with a 50-mile southern branch to Ripley.

The area surrounding the project site also played an important role during WWII as part of the infantry and artillery DTC/C-AMA. In addition to Camp Rice and the Rice AAF, the 3d Armored Division used Camp Iron Mountain and Camp Granite, at the SR 62/177 intersection, about 17 miles west of the project site, from 1942-44. Camp Iron Mountain was designated as an Area of Critical Environmental Concern (ACEC) for its cultural significance in 1980, and is perhaps the best known and certainly the best preserved of all the training camps. Despite the ravages of time, a contour map, many rock mosaics, two alters, and numerous rock alignments along roads and walkways have survived. The area has been fenced to provide protection from vehicular traffic and both Camp Iron Mountain and Camp Granite are visible to the north and south of SR 62,

The habitat is represented by southwestern basin and range topography, characterized by numerous, generally north-south oriented mountain ranges alternating with valleys and alluvial plains. The terrain surrounding the project site consists of a number of broad shallow valleys that generally trend to the southeast, draining into the Colorado River. These valleys contain five playas or closed basin sinks formed by low-lying obstructions on the valley floor. Desert pavement is common and is often well-developed and present in broad patches. Elevations range between 700 and 1600 feet above mean sea level. Soils range from loose-sandy to coarse-sandy loams on the bajadas and valley floors to cobbles, boulder outcrops, and talus on the mountain slopes.

The Rice Valley is a long shallow valley system that is contiguous with Ward Valley to the northwest. Under more pluvial conditions, these valleys had the potential to overflow their blockades and become a continuous drainage (McCarty 1980, p. 7). The climate of the RSEP project site and vicinity is hot and arid and is classified as sub-humid or sub-

tropical with evaporation greatly outstripping precipitation (McCarty 1980). Summer temperatures from July through September average above 86 degrees Fahrenheit with daytime maximum temperatures often nearing 110 degrees Fahrenheit and ground temperatures exceeding 140 degrees Fahrenheit. Winter temperatures are mild, averaging 50–70 degrees Fahrenheit from December through February. Precipitation is around three inches per year, with substantial annual variability occurring between locations. The range of variability is 0–10 inches.

Sonoran Creosote Bush Scrub is the dominant vegetation community present through most of the eastern Mojave/Colorado Desert, with Desert Saltbush community in the immediate project vicinity. (Keeler-Wolf 2007; Kuchler 1977; Schoenherr 1992; Schoenherr and Burk 2007). Along the Colorado River floodplain, riparian communities are dominated by cottonwood and sycamore trees close to the river, and mesquite in drier parts of the floodplain. Two species of mesquite were key food sources for native inhabitants along the river. Mesquite, along with cottonwood, was also used to make arrow shafts, digging sticks, mortars, and pestles. Dense stands of willow and arrow weed are found bordering the river. Today, this area is used primarily for agriculture and recreation. In portions of the floodplain, saltcedar or tamarisk has replaced much of the mesquite and other native vegetation (Minckley and Brown 1994). The nearest native fish species are found in the main channel of the Colorado River mainly are Colorado pikeminnow, razorback sucker, and bonytail chub. (Minckley and Brown 1994; Moyle 2002). The historic-period settlement and land use pattern of the Rice Valley is largely related to early mining activities and early transportation corridors. Other activities playing minor roles in development of the region include: early expeditions, railroads, construction of the Colorado River Aqueduct, and military training.

Much of the surrounding land is managed by BLM, which allows livestock grazing and a variety of recreational activities. The land surrounding the project footprint, excluding Camp Rice and the former Rice AAF, is relatively undisturbed desert. There are no residences or commercial developments, other than the Iron Mountain Pumping Station (IMPS), within visual range of the project site or surrounding desert lands. The closest services to the project site are at Vidal Junction, approximately 13 miles to the east, at the SR 62/95 intersection. The closest towns with full services are Earp, California and Parker, Arizona, on SR62, approximately 17 miles west of Vidal Junction. The larger towns of Blythe and Twenty-nine Palms are about 65 miles south and 75 miles to the west, respectively.

Geology

The following discussion is primarily excerpted from Spaulding (2009). The RSEP is located within the geomorphic province known as the basin and range, situated in the Rice Valley between the Turtle Mountains to the north and the Big Maria and Little Maria Mountains to the south. The geomorphic landscape consists of a broad bajada (a coalescing of neighboring alluvial fans into a single apron of deposits) from the Turtle Mountains, with parallel drainages of parallel rills, gullies, and washes flowing south-southwest toward a dune field southwest of the project area.

The underlying geology consists of alluvial deposits derived from Quaternary dune sands, and recent alluvium composed of sand, silt, clay, and gravel. These range from

Pleistocene (1 million years old) to Holocene (8,000 BC to Recent) in age. Holocene alluvium less than 11,000 years old often is similar to older Pleistocene alluvium. It is typified by moderately to poorly bedded sands, silts, and gravels.

Quaternary alluvium, composed of eolian sand sheets/dunes, locally derived fill, and disturbed sediment mantles underlies most of the proposed receiver tower/heliostat and transmission line. Alluvial fans extending south from the Turtle Mountains contain fine-grained clasts (coarse gravel and finer clastic sediment). Within the heliostat field, they are uniformly fine-grained sediments.

Hubbs and Miller (1948, pp. 90, 164) observed that Late Pleistocene Lake Ward occupied the Danby Dry Lake Basin, northwest from Rice, while Lake Amboy was present in the Bristol-Cadiz Dry Lake Basins. These lakes may have been interconnected, and possibly provided a drainage route from the Death Valley-Mohave River pluvial lakes into the Colorado River (also see Enzel et al. 2003; Gallegos et al. 1980, pp. 22-30). However, only Danby Lake has evidence (the presence of former shorelines) for an expanded pluvial lake (Gallegos et al. 1980; Hubbs and Miller 1948; Smith and Street-Perriott 1983, p. 200; Thompson 1929, p. 708). Lake Ward in the Danby Basin may have been up to 59.5 m deep (Gallegos et al. 1980, pp. 27-28). Williams and Bedinger (1984) concluded Bristol, Cadiz, and Danby Lakes contained Late Pleistocene-Early Holocene marshes.

Paleoclimate and Paleoenvironment

Information on paleoclimate and paleoenvironment for the southern Mojave and northern Sonoran (Colorado) deserts are derived primarily from plant macrofossils found in packrat middens (Cole 1986; Grayson 1993; Spaulding 1990; Tausch et al. 2004; Thompson 1990; Van Devender 1990; Wigand and Rhode 2002, pp. 332–342; Cole 1986; West et al. 2007, pp. 30–33), and stratigraphic studies of playa and dry lake deposits years (Enzel et al. 1989, 1992, 2003; Gallegos et al. 1980, pp. 22-30). The Holocene, the geologic epoch following the Late Pleistocene during which humans probably first occupied North America, began approximately 12,000 years ago. For purposes of this discussion, it is divided into four periods: Early, Middle, Early Late, and Late Late.

Early Holocene (10,000-6,000 BC)

During the Late Pleistocene-Early Holocene, as the climate became warmer and drier, extensive lowland conifer woodlands retreated upslope and were replaced by desert scrub associations. In the northern Sonoran Desert, around 9,500 BC, hot desert plants (Mormon tea, desert thorn, cactuses, Joshua tree, pigmy cedar, cat claw acacia) began dispersing into the region, replacing cooler desert taxa (sagebrush, rabbitbrush, shadscale). From about 8,400 BC on, creosote bush white bursage, and other desert thermophiles began appearing. This warmer drier period, however, also was characterized by episodes of greater precipitation. In the Mohave Desert, three high lake-stands have been identified at Silver Lake playa, dating between 13,000 and 7,300 BC (Enzel et al. 1989). Gallegos et al. (1980, p. 93) postulate that two moister climatic intervals, dating between 11,500 and 12,500 years ago, occurred, based on a pair of caliche beds near Cadiz Dry Lake that contained flaked stone artifacts.

Middle Holocene (6,000-3,500 BC)

The Middle Holocene was the warmest, driest part of the entire Holocene, and has been referred to as the Altithermal (Grayson 1993). Desert shrub vegetation dominated lowland and mid-level elevation localities. White burrobush and creosote bush greatly increased in abundance. A dearth of vegetation data from the Middle Holocene suggests plant cover was probably very sparse as a consequence of severe drought conditions. Between approximately 4,800 and 3,000 BC, little evidence exists for summer rainfall. Gallegos et al. (1980, p. 93) suggest a wetter climatic interval, dating around 8,000 to 8,500 years ago, probably filled desert lakes, based on the presence of a site dating from that time located in the fossil dunes near Bristol Dry Lake.

Early Late Holocene (3,500 BC–1 AD)

The Early Late Holocene has been characterized as a period of relatively cooler, moister climate, interspersed with evidence of warmer drier (sometime drought) conditions. This period has been termed the Neoglacial. Peat deposits, dating to about 5,000 years ago, occur at various spring localities in the Mojave Desert. Around 1,800 BC, a significant increase in the density of pinyon-juniper woodland occurred in southern Nevada, suggesting cooler temperatures and *winter*-precipitation. Denser vegetation appears to have characterized the period between c. 2,000 B.C. and A.D. 1.

A high lake-stand at Silver Lake occurred at approximately 1,620 BC (Enzel et al. 1989, 1992). Gallegos et al. (1980, p. 93) conclude wetter climate occurring about 3000 years ago, produced lake filling, based on evidence of shoreline camp sites at Cadiz Dry Lake. It would have formed a marshy, shallow lake in the Cadiz Dry Lake Basin, containing resources favorable for lakeshore hunting and gathering. However, use of Danby Dry Lake to the southeast probably was limited by its probable high salt content (Gallegos et al. 1980, p. 28).

Late Late Holocene (AD 1–present)

During the Late Late Holocene, temperature and precipitation patterns fluctuated widely. Periods of *summer*-dominant precipitation and milder winters, occurred, contrasting with periods of cooler, somewhat drier conditions and increased *winter*-precipitation. The most significant period of warmer, drier climate, the Medieval Climatic Anomaly, occurred c. 1,200-800 years ago (Meko et al. 2001; Stine 1994, 1996, 1998, 2000). Cooler, wetter climate, dominated from about 1,600 to 1,200 B.P., and again during the Little Ice Age approximately 650 to 150 years ago (Fagan 2000; Grove 1988; Meko et al. 2001; Scuderi 1987a, 1987b, 1990, 1993). Cooler, wetter climatic episodes expanded pinyon-juniper woodland, while warmer, drier conditions favored expansion of saltbush and the creosote bush/white burrobush associations in the lowlands. Enzel et al. (1989, 1992) note a highstand occurred at Silver Lake approximately 390 B.P., corresponding to the Little Ice Age.

Prehistory

During the 1970s, the Bureau of Land Management conducted a large-scale cultural resources inventory of the Central Mojave and Colorado Desert Regions (Gallegos et al. 1980). In an overview of the region, Crabtree (1980) summarized the history of archaeological study, plotted the cultural chronology, identified common site types, and

outlined research topics of interest at the time. Subsequent regional overviews cultural resources management investigations have contributed additional information refining our understanding of the prehistory of this region (cf., Arnold et al. 2002, pp. 43–48; Basgall 1993; Gilbreath and Hildebrandt 1997; Love and Dahdul 2002; Schaefer 1994; Schaefer and Laylander 2007; Schroth 1994; Sutton 1988, 1996; Sutton et al. 2007; Warren 1984; Yohe 1992).

Regional Chronology and Culture History

An initial cultural chronology-culture history scheme for the Colorado Desert was developed in the 1930s and 1940s (Campbell 1931, 1936; Campbell and Campbell 1935; Campbell et al. 1937; Rogers 1939, 1945). This scheme formed the foundation for subsequent efforts, most recently expressed by Sutton et al. (2007, pp. 233–243, table 15.4), relating the temporal periods and complexes delineated to those found in the Mojave Desert. The presentation below of the culture history of the RSEP region is largely drawn from this source.

Paleo-Indian Period (about 10,000–8,000 BC)

In the Southern California deserts, the Paleo-Indian Period dates to the first half of the Early Holocene, and possibly earlier (cf., Beck and Jones 1997; Dillon 2002; Erlandson et al. 2007; papers in Graf and Schmitt 2007; Grayson 1993, pp. 236-244; Jones and Beck 1999; Moratto 1984, Chapters 2 and 3; Rondeau et al. 2007; papers in Willig et al. 1988). This early period is characterized by the presence of various types of leaf-shaped, often fluted, lanceolate, and stemmed points, assigned to the Clovis and Western Pluvial Lakes Traditions. The Clovis Tradition generally dates earlier, and is characterized by large fluted and square-based spear points, large bifaces, heavy core tools, backed scrapers, burins, and graters. Stemmed point (Western Pluvial Lake Tradition) assemblages usually date later in time, and include slightly-shouldered stemmed points, crescents, and other percussion-made bifacial tools, along with ground stone tools. These assemblages often occur in lowlands, and along former pluvial lakeshore margins. Presence of a possibly earlier tool assemblage has been claimed for artifacts recovered from the Calico site.

Dating of fluted and stemmed points in the Southern California desert is complicated by their frequent occurrence as surface finds. A number of sites have produced fluted or stemmed points. Among the most noteworthy Southern California sites are the China Lake site, the Lake Mojave and Pinto Basin localities, and the Awl, Henwood, Rogers Ridge, and Stahl sites (Beck and Jones 1997). It has been suggested that Paleo-Indian peoples were highly mobile, and repeatedly occupied preferred sites. A preference for lowland occupation and increasing use of upland habitats through time is suggested. A possible early emphasis upon hunting large, sometime extinct, terrestrial mammals, and exploiting marsh resources appears to have shifted through time to increased use of seeds and other plant resources along with small game.

Lake Mojave Complex (8,000–6,000 BC)

The Lake Mojave complex, also known as the Western Pluvial Lakes/Western Stemmed Tradition (Beck and Jones 1997; Erlandson et al. 2007; papers in Graf and Schmitt 2007; Schaefer 1994, pp. 63–64; Sutton et al. 2007; papers in Willig et al. 1988), occurs during the second half of the Early Holocene. It is characterized by Great Basin

Stemmed Series projectile points (Lake Mojave and Silver Lake types), abundant bifaces, steep-edged unifaces, crescents, and occasional cobble tools and ground stone tools. These artifacts often occur in undated surface contexts. Assemblage composition and site structure suggest highly mobile foragers, often traveling considerable distances. Little reliance upon vegetal resources is evidenced. The value of wetland habitats remains unclear. Lake Mojave lifeways may result from relatively rapidly changing climate and habitats during the Early Holocene. This would have produced unpredictability in resource distribution and abundance, producing a high degree of residential mobility.

Deadman Lake Complex (7,500–5,200 BC)

Currently, the Deadman Lake complex appears confined to the Twenty-nine Palms area. Sites usually are surficial and located on old alluvial pediments. Artifacts include small-to-medium-size contracting stemmed or lozenge-shaped points, large concentrations of battered cobbles and core tools, and abundant bifaces, simple flake tools, and ground stone tools. The abundance of cobble tools suggests an emphasis upon plant processing. The Deadman Lake and Pinto complexes may represent two different human populations practicing different seasonal/annual rounds, or Deadman Lake may represent a component of the overall Pinto complex adaptation.

Pinto Complex (8,000–3,000 BC)

The Pinto complex spans portions of the Early and Middle Holocene. Toolstone use, based on sites attributed to this complex, focus upon materials other than obsidian and cryptocrystalline silicate (CCS). Pinto Series points are stemmed with indented bases, and display high levels of reworking. Bifacial and unifacial cores/tools are common. Ground stone tools are moderately to very abundant, indicating greatly increased use of plant resources. Pinto sites occur in a broad range of topographic and environmental settings, especially within remnant pluvial lake basins. Moderate to large numbers of people, practicing a collector subsistence strategy, occupied large residential base camps for prolonged periods. Logistical forays into surrounding resource patches probably were made from these sites.

Possible Abandonment (3,000–1,000 BC)

Beginning roughly at this time, conditions in the Mojave Desert were warmer and drier. Few archaeological sites date to this period. This suggests population densities were very low. It is possible some areas were largely abandoned. This period corresponds, in part, to the latter portion of the proposed “Altitheermal Abandonment,” recognized by some prehistorians as characterizing portions of the Great Basin (see Kelly 1997, pp. 8–9).

Gypsum Complex (1,000 BC–AD 200)

The Gypsum complex, spanning most of the Early Late Holocene, is characterized by the presence of corner-notched Elko Series points, concave-base Humboldt Series points, and well-shouldered contracting-stemmed Gypsum Series points. Numerous bifaces also occur. Manos and metates are relatively common. During the early portion of the Gypsum complex, settlement-subsistence appears focused near streams. At this time, increased trade and social complexity apparently occurred. Gypsum components

are smaller, more abundant, and occur over a more diverse suite of settings than those dating previously. Evidence for ritual activities include quartz crystals, paint, split-twig animal figurines, and rock art. Gypsum sites are uncommon in the southern and eastern Mojave Desert.

Rose Spring Complex (AD 200–AD 1000)

Cultural systems profoundly changed in the southern California deserts during Late Late Holocene with the introduction of the bow and arrow, represented by Rosegate Series points. During this time, a major increase in population is thought to have occurred, possibly resulting from a more productive environment and a more efficient hunting technology. Sites often are located near springs, along washes, and sometimes along lakeshores. Intensive occupation is indicated by the presence of wickiups, pit houses, and other types of structures. Well-developed middens have yielded artifact assemblages containing knives, drills, pipes, bone awls, various ground stone tools, marine shell ornaments, and large amounts of obsidian. Obsidian procurement and processing apparently significantly structured settlement-subsistence. During the middle of this period, a major drought (the Medieval Climatic Anomaly) occurred, resulting in hypothesized resource shortages.

Late Prehistoric Period (AD 1000–AD 1700)

During the Late Prehistoric period, horticultural practices and pottery were introduced (most likely from the Hohokam area in southern Arizona or from northern Mexico), having its greatest impact along the Lower Colorado River (McGuire and Schiffer 1982; Schaefer 1994, pp. 65–74; Schaefer and Laylander 2007, pp. 253–254). Ceramic artifacts began to appear in the Colorado Desert approximately AD 1000, assigned to the Lowland Patayan (Lower Colorado Buff Ware) and Tizon Brown Ware traditions (Lyneis 1988; Waters 1982).

A complex cultural landscape composed of rock art, trails, and geoglyphs (explained below) developed during the Late Prehistoric period. Trade and exchange were elaborated, with an emphasis on links between coastal southern California and the Southwest. In addition to pottery, artifact assemblages include Desert Series projectile points, shell and steatite beads, and a variety of milling tools. Obsidian use declines significantly, with CCS becoming the dominant toolstone.

Prehistory of the Rice Valley

Prehistoric sites in the immediate vicinity of the RSEP are rare, most likely attributable to the lack of a stable water supply throughout prehistory. It is unclear whether there was ever a fresh water supply. However, seasonal vegetation patterns suggest that past peoples inhabiting the area were very mobile. During early historic times, native peoples inhabited towns/hamlets located along the Colorado River, within the Coachella Valley, and at major desert springs/oases.

Prehistoric Research Topics

Prehistoric research topics include chronology, subsistence-settlement, technological organization, and trade and exchange.

Cultural Chronology

Concerns regarding prehistoric projectile point typology in the Southern California desert have been focused upon the contention that broken, reworked projectile points assigned to one type may produce points assigned to another, possibly obviating their usefulness as chronological markers. This is the Flenniken Challenge (cf., Arnold et al. 2004, p. 45). Dating Early Holocene points is complicated by their frequent occurrence as surface finds. Attempts to date them using obsidian hydration has produced varying results (cf., Basgall 1993, 1995; Jenkins 1987; Jenkins and Warren 1984; Schroth 1994). The chronological parameters and function(s) of Elko, Rosegate, and Humboldt points also have been issues (Bettinger and Eerkens 1997, 1999; Garfinkel and Yohe 2004; Yohe 1992, 1998, 2000). Of particular interest is introduction of the bow-and arrow sometime around A.D. 500.

The Middle Holocene has been viewed by some as a period during which most people left the Great Basin as a consequence of warmer, dryer climate, the so-called Altithermal Abandonment (cf., Antevs 1948; Baumhoff and Heizer 1965; Grayson 1993; Kelly 1997; Madsen 2002; Rhode 1999). This time is characterized by decreased archaeological visibility, suggesting people either were drawn to localities with more reliable resources, or migrated out of the Great Basin to more productive areas.

The Late Holocene is marked by a substantial increase in the number of archaeological sites and greater numbers of artifacts, suggesting increased populations as well as population movements. These include the Anasazi Intrusion into southern Nevada/southwest Utah, focused upon the Virgin and Muddy River Valleys (cf., Kelly 1997; Larson 1987, 1996; Larsen and Miichaelson 1990; Lyneis 1992, 1994, 1995). On a larger scale was the apparent expansion of Numic-speaking peoples throughout much of the Great Basin (Bettinger and Baumhoff 1982; Grayson 1993; Kelly 1997; papers in Madsen and Rhode 1994). This is marked by changes in pottery, basketry, projectile points, and other artifacts. The Late Holocene also marked introduction of Hakataya/Lowland Patayan Ceramic Series buffware pottery into the Colorado Desert/Salton Basin (Arnold et al. 2004; Love and Dahdul 2002; Schaefer and Laylander 2007; Schroeder 1958, 1979; Waters 1982). Contemporaneous use of Tizon Brownware pottery in the Peninsular Ranges and along the Pacific Coast also occurred (Lyneis 1988; Griset 1996).

Subsistence-Settlement

In the Southern California desert, prehistoric subsistence-settlement strategies can be regarded as expressions of Holocene Archaic "Broad Spectrum" adaptation marked by increasing dependence through time upon exploitation of an extremely diverse suite of resources, and increasingly complex resource procurement behavior (cf., Arnold et al. 2004; Basgall 2000; Bettinger 1993, 1999; Elston 1982, 1986; Hockett 2007; Kelly 1995, 1996, 1997; Sutton 1996; Simms 1986, 1987; Thomas 1983a, 1983b; Warren 1984; Warren and Crabtree 1986). This is manifested by development through time of resource and land use intensification (cf., Barlow and Metcalfe 1996; Bettinger 1993, 1999; Elston and Zeanah 2002; Kelly 1997, 2001; papers in McGuire 2002; McGuire et al. 2004; Metcalf and Barlow 1992; Simms 1985a, 1985b, 1987; Thomas 1983a, 1983b, 1988; Zeanah 2004; Zeanah and Simms 1999).

These factors have expressed themselves in Holocene development of hunting and

gathering practices. The focal point of the former has been the emphasis upon taking large versus small game animals, with causative factors including resource depression and intensification, climatic change, and social signaling (cf., Broughton and Bayham 2003; Broughton et al. 2008; Byers and Broughton 2004; Byers and Smith 2007; Byers et al. 2005; Coddington and Jones 2007; Hildebrandt and McGuire 2002; Hockett 2005, 2007; Hockett and Murphy 2009; McGuire and Hildebrandt 2005; McGuire et al. 2004, 2007; Ugan 2005a, 2005b; Ugan and Bright 2001). Gathering studies have emphasized pine nut and hard seed utilization, with transport and processing costs, increased use of upland habitats, and sexual division of labor viewed as critical issues (cf., Bettinger 1993, 1999; Hildebrandt and Ruby 2006; Kelly 1997, 2001; Thomas 1983a, 1983b, 1988; Zeanah 2004; Zeanah and Simms 1999).

Prehistoric hunting and gathering may have led to the evolution of hunting and/or gathering “landscapes”, which influenced the location, distribution, and configuration of habitation sites and task sites utilized for specific resource procurement (cf., Basgall 2000; Bettinger 1999; Eerkens 1999, 2003 b & c, 2004; Fowler 1985, 1994, 1995, 1996; Gilreath and Hildebrandt 1997; Simons 2009; Simons et al. 2009; Zeanah 2004; Zeanah and Simms 1999). Through the Holocene, group mobility decreased and the length of site occupancy increased as growing population size appears to have increased territoriality and decreased foraging territory size (Arnold et al. 2004; Bamforth 1990, Basgall 2000; Bettinger 1999).

Eerkens (2003c; 2004) suggests a significant increase in small seed use and the advent of brownware pottery around AD 1300–AD 1400 are linked. Seed use was intensified because seeds could easily be individually owned, and not subject to unrestricted sharing. Pots were a critical component of small seed intensification, because they usually were individually made and owned, and could be used within houses, allowing food preparation and consumption to occur in private. Privatization of small seeds may have resulted from increased population size, which produced more potential “freeloaders,” new community kinship structures, and creation of resource surpluses.

Horticulture/Agriculture

At the time of initial Euroamerican contact approximately 240 years ago, native peoples living along the Colorado River and within the Colorado Delta grew a wide variety of domesticates and wild grasses, which provided 30-50 percent of their subsistence economy (Castetter and Bell 1951; Schaefer and Laylander 2007, pp. 253-254). Annual flooding of the Colorado River rejuvenated the soil, and provided enough moisture to sustain crops. Colorado River agriculture appears to have begun around 1,300 years ago. It probably was introduced either from the Hokokam area to the east, or from northern Mexico to the southeast (McGuire and Schiffer 1982).

Horticulture appears to have spread west from the Colorado River, possibly reaching the western Colorado Desert 300-200 years ago. Human coprolites and seed caches found in ceramic jars and cache pits from this region contain remains of native cultigens (cf., Bayman et al. 1996; Swenson 1984; Wilke 1978a, 1978b; Wilke and McDonald 1989; Wilke et al. 1977). However, native cultigens may have reached this area through trade instead of local production (Schaefer and Laylander 2007, p. 254).

In the Mojave Desert and adjacent areas, irrigation agriculture was first practiced as a consequence of the Anasazi Intrusion (Kelly 1997; Larson 1987, 1996; Larsen and Michaelson 1990; Lyneis 1992, 1994, 1995; Warren 1984, p. 421, fig. 8.25). It occurred along with foraging for native wild plant and animal resources. Agriculture/horticulture subsequently was practiced by various Numic-speaking peoples, such as the Owens Valley Paiute, Death Valley peoples, Panamint and Timbisha Shoshone, and several Southern Paiute groups, including the Chemehuevi (Fowler 1995:, pp. 110-112, 1996, pp. 91-98; Lawton et al. 1976; Liljeblad and Fowler 1986, pp. 417-418; Steward 1930, 1933, 1938, 1940, 1970; Winter and Hogan 1986, pp. 125-129; Yohe 1997).

Maize, beans, squash, sunflowers, and amaranth were grown in gardens near springs, irrigated communal fields and garden plots, and along streams. Land management and plant husbandry techniques directed at non-domesticates included burning to encourage growth of new plants, clearing, pruning, and coppicing, transplanting plants, broadcast seed sowing, and irrigation of wild stands of bulb and seed plants. Mojave Desert agriculture/horticulture has been interpreted as a response to increased population pressure during late prehistoric times, possibly resulting from climatic change and/or immigration (Bouey 1979).

Cultural Landscapes

In the Colorado and Mojave Deserts, trails, cairns, geoglyphs, cleared circles, rock rings, other desert pavement features, rock art sites, and artifact scatters appear to be elements of prehistoric-ethnohistoric cultural landscapes⁴ (Gilreath 2007; Schaefer and Laylander 2007, pp. 254–255; Cleland and Apple 2003; Cleland 2007). Geoglyphs were constructed on desert pavements by rearranging and/or clearing pebbles and rocks to form alignments, clearings, and/or figures (Arnold et al. 2002; Gilreath 2007, pp. 288–289; Solari and Johnson 1982). These “gravel pictographs” and rock alignments (Harner 1953) occur throughout the deserts of southeast California and adjacent portions of southern Nevada and western Arizona. Rock alignments are present throughout this region, while representational figures only occur close to the Lower Colorado River. An elaborate system of prehistoric-ethnohistoric trails crossed the southern California deserts, leading to or passing adjacent to many of these features (cf., Davis 1961; Earle 2005; Johnson 1980; Johnson and Johnson 1957; Sample 1950; von Werlhof 1988)

Colorado Desert localities include the Pilot Knob Complex, the rock art complex at Palo Verde Point, the Ripley Locality, the Quien Sabe-Big Maria complex, the Topock Maze (Rogers 1929), and a few dozen giant ground figures (Harner 1953; Setzler and Marshall 1952), often first observed from the air. In the Mojave Desert, large rock alignments are found in Panamint Valley, Death Valley, Eureka Valley, and the Owens River Valley (Davis and Winslow 1965; Gilreath 2007, pp. 288–289; von Werlhof 1987). Cation ratio dating⁵ of desert varnish has provided estimated ages of approximately AD

⁴ Cultural landscapes, when related to specific ethnic groups, are referred to as Ethnographic Landscapes (Hardesty 2000).

⁵ Cation ratios between weathered rock varnish and unweathered rock are used as a relative dating technique to roughly determine the age of prehistoric rock carvings (petroglyphs). The quantity of positively-charged ions within the varnish (a chemically-changed layer built up of calcium and potassium leachate over time) is compared to those within the unweathered rock beneath the varnish.

800–AD 1000 for the Colorado geoglyphs (Dorn et al. 1992; Schaefer 1994, p. 63; von Werlhof 1995), although use of the technique remains controversial (Gilreath 2007, p. 289).

These geoglyph, rock alignment, and rock art sites may represent prehistoric ceremonial centers, located along routes between sacred places, representing creation/origin stories/myths, cosmology, iconography, and religion of prehistoric peoples (Altschul and Ezzo 1995; Cleland 2005; Ezzo and Altschul 1993; Gregory 2005; Hedges 2005; Johnson 1985, 2003; von Werlhof 1995, 2004; Whitley 2000; Woods et al. 1985). They also may have functioned as focal points for shamanistic activities, vision quests, curing, and group rituals/ceremonies. Their construction has been interpreted as resulting from group ritual(s) (von Werlhof 1987). Many appear characterized by multiple-use episodes, with portions added through the years as part of ongoing rituals/ceremonies.

Symbolic activities also were represented by intentional pot-drop distributions along trails near water sources. The importance to Native Americans of water sources for survival during long-distance trips and seasonal rounds is obvious. Water sources also manifested significant spiritual values and often were associated with major rock art complexes (McCarthy 1993; Schaefer 1992).

Technological Organization

Prehistoric quarry/lithic artifact manufacture behavior in the Mojave Desert is manifested by differences in tool manufacture and behavior related to the presumed user's gender (Welch 2000), formal versus the expedient procurement of tool stone (Wilke and Schroth 1989); and scales of production occurring at ground stone tool quarries (Schneider et al. 1995). Bamforth (1990, 1992) considers Holocene settlement, raw material, and lithic procurement at several quarry sites in the central Mojave Desert. He suggests prehistoric quarry use was conditioned upon mobility strategies, regional quality and abundance of tool stone, as well as quarry location. Bamforth suggests that an emphasis on transporting prepared cores during the period 2,000 BC–AD 500 may have resulted from the formation of relatively large and stable communities in areas with concentrated plant resources. Basgall's (2000) study of tool stone use during the Late Pleistocene-Early Holocene concluded tool stone selection mainly reflected functional attributes of various tool stone types.

With respect to social and cultural factors governing pottery adoption and use within the Southern California deserts, one concern has been determining if ceramic vessels were locally made (Eerkens 2001; Eerkens et al. 1999, 2002a, 2002b; Griset 1996). Pots generally appear to have been locally produced and used, with limited exchange of pots between different groups. Production appears to have been organized at an individual or family level, emphasizing production of largely utilitarian wares.

Pottery from northern Mojave sites has a relatively high number of elemental signatures suggesting high levels of residential mobility (Eerkens 2003b; Eerkens et al. 2002b). Additionally, prehistoric people produced a fairly large number of pots. The combination of high mobility and a fairly high level of pottery production is seen as leading to caching

pots near lowland wetlands, which were fixed in the landscape, development of pottery attributes promoting fuel consumption, and a high degree of standardization of largely utilitarian ceramics.

Trade and Exchange

Prehistoric and ethnohistoric Southern California desert peoples had a highly developed network of trail connections linking locations within and beyond the region (cf., Davis 1961; Earle 2006; Johnson 1980; Johnson and Johnson 1957; Sample 1960; von Werlhof 1988). High mobility produced considerable cross-cultural interaction and integration in spite of frequent open aggression and warfare between different groups. This integration and interaction occurred between mobile hunter-gatherers and sedentary horticultural peoples. They are archaeologically manifested by the spatial distribution of site types, rock art, artifacts (especially ceramics and shell ornaments), and tool stones, especially obsidian.

Archaeologists monitor the dynamics of prehistoric trade in the Southern California desert by analyzing distributions of artifacts made from various tool stones, shell beads and ornaments, and ceramic types and composition (Schaefer and Laylander 2007, pp. 255–256). Radiocarbon dates ranging between 11,200 and 7860 B.P. on shell beads from several Mojave Desert sites indicate regional trade began early (Fitzgerald et al. 2005). Jones et al. (2003) note Early Holocene desert peoples may have had foraging territories 200-300 km on a side.

The Southern California desert provided prehistoric peoples with a variety of lithic materials for artifact production. These included obsidian, cryptocrystalline silicates (chert), crystalline volcanics (basalt, rhyolite), quartz, and plutonic, metamorphic, and sedimentary rocks. Coso obsidian was the dominant source of obsidian used by desert peoples prior to c. AD 700 when its use dramatically declined (Arnold et al. 2004; Eerkens and Rosenthal 2004; Ericson 1989; Gilreath and Hildebrandt 1997; Hughes 1988; Mazer et al. 1991; Rhode 2000; Stevenson and Sheetz 1989; Stevenson et al. 1993).

Other obsidian sources in the southern Mojave Desert include Bristol Mountains and Devil Peak (Shackley 1994). Johnson and Wagner (2005) and Johnson and Haarklau (2005) note obsidian from a host of sources located along the boundary between the northernmost Mojave Desert and the south-central Great Basin were utilized. Approximately a dozen sources located in Baja California, extreme northwest Sonora, and western Arizona also possibly were used (McFarland 2000; Shackley 1988, 1995, 2005). During the last thousand years, Obsidian Butte glass became the principal obsidian used in the Colorado Desert and coastal southern California (Hughes 1986; Hughes and True 1983; Laylander and Christenson 1988; Schaefer and Laylander 2007, p. 251).

Artifacts made from shellfish species inhabiting the northern Sea of Cortez occur in coastal southern California and the Great Basin (Bennyhoff and Hughes 1987; Fitzgerald et al. 2005) and may have been traded through the Colorado Desert (Schaefer and Laylander 2007, p. 255). Shells from southern California coastal species occur at a number of Southern California desert sites and at others in the Southwest

(Ford 1983). Late Period interregional connections are suggested by the frequent occurrence of Lower Colorado Buffware (i.e., Patayan/Hakataya) pottery throughout the Colorado Desert (Cordell 1997; McGuire 1982; Plymale-Schneeberger 1993; Schaefer and Laylander 2007, p. 255; Schroeder 1979; Shaul and Hill 1998; Waters 1982).

Ethnographic Background

The Chemehuevi are the most likely Native American group ethnohistorically inhabiting the Ward/Rice Valley region. Adjacent groups included the Serrano, Cahuilla, Mojave, Maricopa, and Halchidhoma. The Rice project area is located within the southern part of Chemehuevi territory. Mohave territory was to the east. The Las Vegas group of Southern Paiute were to the north-northwest. The Serrano were to the west-southwest.

The Chemehuevi

Sources for the Chemehuevi include Drucker (1937), Kelly (1934; 1936), Kelly and Fowler (1986), Kroeber (1925, pp. 593–600), Miller and Miller (1967), and Roth (1976; 1977). Carobeth Laird married a Chemehuevi and collected a large corpus of data, primarily on ritual, religion, and myth (Laird 1974a; 1974b; 1975a; 1975b; 1976; 1977a; 1977b; 1977c; 1978a; 1978b; 1984). The Chemehuevi spoke a language belonging to the Southern Group of the Numic subfamily of the Uto-Aztecan family (Golla 2007; Moratto 1984; Shipley 1978). Many traits characterizing Chemehuevi culture are very similar or identical to those of the Mohave, discussed below. Several probable Quechan traits also were noted for the Chemehuevi.

For the territory traditionally claimed by the Chemehuevi, the Colorado River formed the eastern boundary south to the Palo Verde Mountains. The boundary then ran northwest, passing east of the Ironwood Mountains, crossing the middle of the Maria Mountains, paralleling the east side of the Iron Mountains, and then running between Old Woman Mountain and just east of Cadiz Dry Lake (Kelly 1934; Kelly and Fowler 1986, p. 369, fig. 1).

The Chemehuevi lacked any form of overall “tribal” organization. Anthropologists refer to territorial subdivisions among the Chemehuevi as “bands.” Each band was composed of a small number of camps/communities/villages. Bands most likely corresponded to economic clusters (Kelly 1964). Each group was a geographic unit, associated with a definite territory. In general, each band was economically self-sufficient.

In general, Chemehuevi settlement was mobile and scattered, with residence recurring within a fixed area. Houses were closely grouped. Their occupants usually were related by blood or marriage. Settlement size ranged from 1–2 households up to 10–20. Springs often were inherited private property. Married siblings often camped at the same spring.

The Chemehuevi traveled widely. They had amicable contact with the Serrano, Cahuilla, Quechan/Yumans, and other Native American groups. The Chemehuevi sometimes joined with the Mohave/Quechan to fight the Cocopa/Halchidhoma. The Chemehuevi often crossed the Colorado River and hunted deer in Quechan, Yavapai, and Western Walapai territory. They also traded, intermarried, and competed in games with the Yavapai. To the west, the Chemehuevi hunted in the Tehachapi area and went

to the Pacific Coast along the Santa Barbara Channel to get abalone shell. Sometimes, a party of 8–10 Chemehuevi men joined men from neighboring groups to make a two-month journey to the Hopi villages (in what is now New Mexico) to trade.

The Chemehuevi apparently did not eat fish, but bighorn sheep, deer, pronghorn antelope, and desert tortoise were among the animal food resources they used (Kelly and Fowler (1986, p. 369). Plant foods in this region included pinyon nuts and mescal. Men inherited rights to hunt large game within certain tracts, defined in songs using geographic references. Women gathered a great variety of plant foods, which were more important in the Chemehuevi diet than game. In addition to pinyon nuts and mescal, agave and seeds were staples. Along the Colorado River, the Chemehuevi practiced floodplain agriculture. They grew corn, squash, gourds, beans, sunflowers, amaranth, winter wheat, grasses, and devil's claw using techniques similar to Mohave agricultural practices (see below).

Chemehuevi winter houses were conical/sub-conical structures. They also built earth-covered houses without a front wall, similar to those constructed by the Mohave. During the summer, many Chemehuevi lived outside, often building and occupying armadas and windbreaks.

With respect to material culture, Chemehuevi baskets and cradles were made from plant fibers. Plant fibers also provided materials for rope, string, and cordage nets. Pottery, which followed Mohave patterns and styles, included cooking pots, water jars, seed germination and storage pots, spoons/scoops, and large pots for ferrying children across the Colorado River. Watercraft included log rafts and reed balsas. Clothing consisted of double skin or fiber aprons and sandals for men and women. The Chemehuevi commonly had pierced ears and wore body paint.

Monogamy was the commonest form of marriage among the Chemehuevi, but some men had more than one wife. Women gave birth in a special enclosure, followed by a 30-day period of seclusion for mother, father, and child. Puberty rites for boys and girls were held, with the former focused on acquisition of hunting skills. Cremation of the dead was traditional, replaced by in-ground burial in the historic period.

In general, no central political control existed. Territorial boundaries were not rigid, and some bands were named, while others were not. The closest known Chemehuevi tribal unit to the RSEP project area is in the Providence Mountains (roughly 90 miles northwest), named "Tumpisagavatsits" or "Timpashauwagotsits" (Kroeber 1925, p. 595). The basic social and economic unit was the nuclear family and could include other close kin. Groups of individual households moved together on hunting and gathering trips, returning to the same spring or agricultural site. Most large bands had a headman whose leadership was more advisory than authoritative. He was usually succeeded by his eldest son.

The principal role of Chemehuevi shamans was curing illness. They acquired their healing powers through dreams rather than through the use of datura or a trance. Chemehuevi families held a mourning ceremony ("cry"), with which several speeches and songs were associated, within the year after the death of a relative. The "cry" was sponsored by the family and included the ceremonial burning of material goods.

The Chemehuevi had deer and mountain sheep song-dances, held for entertainment and hunting success. The Chemehuevi had other songs, as well: bird, salt, quail, and funeral songs. During winter evenings, men narrated a rich body of traditional stories and myths. These performances often included mimicry, song, and audience participation. Oral tradition related people to social norms, their territories, and to the subsistence resources present within them.

The Serrano

Sources for the Serrano include Bean and Smith (1978), Benedict (1924,1929), Drucker (1937), Gifford (1918), Johnston (1965), Kroeber (1925, pp. 615–619), and Strong (1929, pp. 5–35). The Serrano shared many traits and artifacts with the Cahuilla, discussed above. The Serrano spoke a language belonging to the Serean Group of the Takic subfamily of the Uto-Aztecan family (Golla 2007; Moratto 1984; Shipley 1978).

It is nearly impossible to assign definite boundaries to Serrano territory. Territory traditionally claimed by the Serrano included the San Bernardino Mountains east of Cajon Pass, lands at the base and north of the San Bernardinios in the desert near Victorville, and territory extending east in the desert to Twenty-nine Palms and south to, and including, the Yucaipa Valley.

The Serrano occupied small village-hamlets located mainly in the foothills near water sources. Others were at higher elevations in coniferous forest, or in the desert. The availability of water was a critical determinant of the nature, duration, and distribution of Serrano settlements.

Women gathered, and men hunted and occasionally fished. Topography, elevations, and biota present within the Serrano territory varied greatly. Primary plant foods varied with locality. In the foothills, they included acorns and pinyon nuts. In the desert, honey mesquite, pinyon, yucca roots, and cactus fruits were staples. In both areas they were supplemented by a variety of roots, bulbs, shoots, and seeds, especially chia. Among primary game animals were deer, mountain sheep, pronghorn, rabbits, rodents, and quail. Large game was hunted with bows and arrows. Small game was taken with throwing sticks, traps, snares, and deadfalls. Meat was cooked in earth ovens. Meat and plant foods were parched or boiled in baskets. Plant foods were ground, pounded, or pulverized in mortars and pestles or with manos and metates. Processed meat and plant foods were dried and stored. Occasional communal deer and rabbit hunts were held. Communal acorn, pine nut, and mesquite gathering expeditions took place. These communal activities involved several lineages under a lineage leader's authority.

Serrano houses were circular, domed, individual family dwellings, with willow frames and tule thatching. They were occupied by a husband and wife along with their children, and often other kin. Houses were mainly used for sleeping and storage. Most daily activities occurred outside, often in the shade of a ramada (a flat-roofed, open-sided shade structure) or other sun cover.

Settlements usually had a large ceremonial house where the lineage leader and his family lived. It was the social and religious center for each lineage/lineage set. The latter was two or more lineages linked by marriage, economic reciprocity, and ritual

participation. Other structures included semi-subterranean, earth-covered sweathouses located near water, and granaries.

Serrano material culture was very similar to that of the Cahuilla. Stone, wood, bone, plant fibers, and shell were used to make a variety of artifacts. These included highly decorated baskets, pottery, rabbit skin blankets, bone awls, bows and arrows, arrow straighteners, fire drills, stone pipes, musical instruments, feathered costumes, mats, bags, storage pouches, cordage, and nets.

The clan was the largest autonomous landholding and political unit. No pan-tribal union between clans existed. Clans were aligned through economic, marital, and ceremonial reciprocity. Serrano clans often were allied with Cahuilla clans and Chemehuevi groups. The core of a clan was the lineage. A lineage included all men recognizing descent from a common ancestor, their wives, and their descendants. Serrano lineages were autonomous and localized, each occupying and using defined, favored territories. A lineage rarely claimed territory at a distance from its home base.

The head of a clan was a ceremonial and religious leader. He also determined where and when people could hunt and gather. Clan leadership was passed down from father to son. The clan leader was assisted by a hereditary ceremonial official from a different clan. This official held ceremonial paraphernalia (the sacred bundle), notified people about ceremonies, and handled ceremonial logistics.

Serrano shamans were primarily healers who acquired their powers through dreaming. A shaman cured illness by sucking it out of the sick person and by the administration of herbal medicines. Various phases of an individual's life cycle were occasions for ceremonies. After a woman gave birth, the mother and baby were "roasted," and a feast held. Differing puberty ceremonies were held for boys (datura ingestion used in a structured ceremonial vision quest) and girls ("pit roasting," ingestion of bitter herbs, dietary restrictions, instruction on how to be good wives). The dead were cremated, and a memorial service was held. During the annual seven-day mourning ceremony, the sacred bundle was displayed, the eagle-killing ceremony took place, a naming ceremony for all those born during the preceding year was held, images were made and burned of those who had died in the previous year, and the eagle dance was performed.

The Cahuilla

A wealth of information exists regarding traditional and historic Cahuilla society and culture (see Bean and Lawton 1967 for a comprehensive bibliography of sources). Primary sources for the Cahuilla include Bean (1972; 1978), Bean and Saubel (1972), Drucker (1937), Gifford (1918), Hooper (1920), James (1960), Kroeber (1908; 1925, pp. 692–708), and Strong (1929, pp. 36–182). The Cahuilla language, divided into Desert, Pass, and Mountain dialects, has been assigned to the Takic subfamily of the Uto-Aztecan family (Golla 2007; Moratto 1984; Shipley 1978).

Territory traditionally claimed by the Cahuilla was topographically complex, including mountain ranges, passes, canyons, valleys, and desert. Bean (1978, p. 375) described it as, "...from the summit of the San Bernardino Mountains in the north to Borrego Springs and the Chocolate Mountains in the south, a portion of the Colorado Desert

west of Orocopia Mountain to the east, and the San Jacinto Plain near Riverside and the eastern slopes of Palomar Mountain to the west.” The natural boundaries of the desert, mountains, hills, and plains separated the Cahuilla from surrounding Native American groups. The Cahuilla interacted with surrounding peoples via intermarriage, ritual, trade, and war. The Cahuilla, Gabrielino, Serrano, and Luiseño shared common cultural traditions, with the Cahuilla having especially close ties to the two former groups.

Cahuilla villages usually were located in canyons or on alluvial fans near water and food patches. The area immediately around a village was owned in common by a lineage. Other lands were divided into tracts owned by clans, families, and individuals. Numerous sacred sites with rock art were associated with each village. Trail networks used for hunting, trading, and social visiting connected villages. Trading was a prevalent economic activity. Some Cahuilla were trading specialists. The Cahuilla went as far west as the Channel Islands and east to the Gila River to trade.

Men hunted deer, mountain sheep, pronghorn, rabbits, rodents, and birds. This game was stalked/pursued/trapped by individuals and communal hunting groups. Blinds, pits, bows and arrows, throwing sticks, nets, snares, and traps were used to procure game. Communal hunts using fire drives sometimes occurred.

The Cahuilla had access to an immense variety of plant resources present within a diverse suite of habitats (Barrows 1900; Bean and Saubel 1972). Several hundred plant species were used for food, manufacture, and medicine. Acorns, mesquite and screw beans, pinyon nuts, and cactus fruits were the most important plant foods. They were supplemented by a host of seeds, tubers, roots, bulbs, fruits and berries, and greens. Corn, beans, squash, and melons were cultivated. Over 200 species of plants were used as medicines.

Structures varied in size from brush structures to dome-shaped or rectangular houses, 15–20 feet long, and ceremonial houses. The chief’s house usually was the largest. Used for many social, ceremonial, and religious functions, it was located near a good water source. It generally was next to the ceremonial house, which was used for rituals, curing, and recreational activities. Other structures included communal men’s sweathouses and granaries.

Mortars and pestles, manos and metates, pottery, and baskets were used to process and prepare plant and animal foods. Cahuilla material culture included a variety of decorated and plain baskets; painted/incised pottery; bows, arrows, and other hunting-related equipment; clothing, sandals, and blankets; ceremonial and ritual costumes and regalia; and cordage, rope, and mats. Games and music were important social and ritual activities for the Cahuilla.

The Cahuilla had named clans, composed of 3–10 lineages, with distinct dialects, common genitors, and a founding lineage. Each lineage owned particular lands, stories, songs, and anecdotes. Each lineage occupied a village and controlled specific resource areas. All clan members jointly owned clan territory. Territory ownership was established by marked boundaries (rock art, geographic features), and oral tradition. Most of a clan’s territory was open to all Cahuilla. Kinship rules determined rights to assets and responsibilities within a lineage. Each lineage cooperated in defense, large-

scale subsistence activities, and ritual performance. The founding lineage within a clan often owned the office of ceremonial leader, the ceremonial house, and sacred bundle. Artifacts and equipment used in rituals and subsistence was owned by individuals and could be sold or loaned.

The office of lineage leader usually passed from father to eldest son. He was responsible for correct performance of rituals, care of the sacred bundle, and maintenance of the ceremonial house. The lineage leader also determined when and where people could gather and hunt, administered first-fruits rites, and stored food and goods. He knew boundaries and ownership rights, resolving conflict with binding decisions. The lineage leader met with other lineage leaders concerning various issues. He was assisted in his duties by a hereditary official responsible for arranging details for performance of rituals. Other functionaries included song leaders/ceremonialists, assisted by singers and dancers.

Laws were enforced by ritual, stories, anecdotes, and direct action. Supernatural and direct sanctions were used. Tradition provided authority. The past was the referent for the present and future. Old age provided access to privilege, power, and honor. Reciprocity was a significant expectation. Doing things slowly, deliberately, and thoughtfully was stressed. Integrity and dependability in personal relations were valued. Secrecy and caution were exercised in dealing with knowledge.

Disputes between Cahuilla villages usually arose over access to resources. Other causes included sorcery, personal insults, kidnapping of women, nonpayment of bride price, and theft. Armed conflict occurred after all other efforts to resolve things had failed. A lineage leader and/or skillful warrior lead a temporary war party. Community rituals were held before and after a fight, which usually involved ambush.

Ritual and ceremony were a constant factor in Cahuilla society. Some ceremonies were scheduled and routine, while others were sporadic and situational. The most important ceremonies were the annual mourning ceremony, the eagle ceremony, rites of passage (especially those associated with birth, naming, puberty, marriage), status changes of adults, and rituals directed towards subsistence resources. The main focus was upon performance of cosmologically oriented song cycles, which placed the Cahuilla universe in perspective, reaffirming the relationship(s) of the Cahuilla to the sacred past, present, to one another, and to all things.

The Mohave

Information regarding the traditional lifeways of the Mohave has mainly been drawn from the accounts of early explorers and/or fur trappers who were among the first to encounter native groups, as well as from the later ethnographic accounts of anthropologists, usually well after the influences of Euro-American contact had begun to alter traditional ways of life. The following summary derives mainly from Kroeber (1925) and Stewart (1983a, 1983b).

The name Mohave is a variation on the name Hamakhava, which is what the tribal people called themselves (Kroeber 1925, p. 727). The Mohave language is classified into the Yuman subfamily of the Hokan language family. The Mohave were the northernmost and largest tribe of the River and Delta Yumans, who comprised a series

of agricultural tribes that occupied the lower Colorado and Gila Rivers. The traditional ethnographic territory attributed to the Mohave includes the Mojave, Chemehuevi, and Colorado River Valleys along the lower Colorado River at the intersection of the borders of Arizona, Nevada, and California. In pre-contact times, Mohave tribal settlement is reported to have centered in the Mohave Valley where their population densities were observed to be the greatest (Stewart 1983b, p. 55).

The Colorado River served as an oasis in the otherwise harsh, dry environment that surrounded the river valleys. The spring overflow of the river, which spread gently over the bottomlands, left behind a rich silt deposit in its recession. It is within these bottomlands that the Mohave cultivated crops, which served as the foundation of their subsistence economy. Their agricultural methods were relatively simple, consisting of planting seeds on the richly silted floodplains and allowing their crops to mature with a minimum of maintenance or effort. Corn was the primary crop, but several varieties of tepary beans, pumpkins, melons, and other plants were also grown. Once harvested, the portions of the harvest that were not immediately consumed were dried in the sun and stored in large basketry granaries. The Mohave supplemented their diet mainly by gathering wild plants and by fishing, which served as their principle source of meat. Hunting played a minor role in the Mohave subsistence economy (Stewart 1983b, pp. 56–59).

Technology of the Mohave was relatively simple, with tools crafted to meet only the minimum requirements of utility (Stewart 1983b, p. 59). According to Kroeber (1925, p. 736), the farming implements consisted of only two items: a heavy wooden staff or digging stick for planting and a spatulate wooden hoe-like implement, whose square edge was pushed flat over the ground to control weeds. Metates, consisting of a rectangular block of stone, were used for grinding corn, wheat, and beans, and both stone and wooden pestles, as well as stone mortars, were also used for food processing (Kroeber 1925, pp. 736–737). Fish were commonly taken with seines, large basketry scoops, sieves, dip nets, and weirs. The bow and arrow and cactus-spine fish hooks were also used for fishing. Mojave basketry was crudely woven, and their pottery was basic and utilitarian (Stewart 1983b, p. 59). Since hunting was of relatively little significance to the Mohave, hunting devices and techniques were not well developed, consisting mainly of snares, nets, bow and arrow, or curved throwing sticks (Stewart 1983b, pp. 59–61).

Mohave political and social organization was very informal, and no one individual or group had significant authority over another. Despite the Mohave's loose division into bands or local groups that were spread out over great distances, their cohesion as a tribe was very strong, and they considered themselves as one people occupying a nation with a well-defined territory (Stewart 1983a, 1983b).

The nuclear family was the basic unit of economic and social cooperation, although the extended family constituted the core of a settlement. Rather than large centralized villages, Mohave settlements were widely distributed along the riverbanks in close proximity to arable lands. Houses were situated on low rises above the floodplain and often separated by as much as a mile or two (Stewart 1983b, p. 57). During most of the year, the Mohave slept under ramadas; however, during the colder season, they occupied more substantial, semi-subterranean, rectangular earth-covered houses.

Warfare was a dominant strain in River Yuman culture, and the Mohave's strong tribal unity served them well in times of warfare. They apparently traveled great distances to do battle, and their principle weapons were bows and arrows and hard wood clubs. According to Kroeber (1925, p. 727), their main motivation was sheer curiosity, as they liked to see other lands and were eager to know the manners of other peoples, but was not heavily interested in trade.

The Mohave were culturally similar to the other River and Delta Yumans: the Quechan, Halchidhoma, Maricopa, and Cocopa. During ethnohistoric times, the Quechan were considered friends and allies of the Mohave, while the Halchidhoma, Maricopa, and Cocopa were considered to be enemies with whom the Mohave engaged in warfare (Stewart 1983b, p. 56). The Mohave were also friendly with the Upland Yuman tribes of the Yavapai and Walapai of western Arizona, although relations with the Walapai were somewhat mixed.

One of the most important rituals observed by the Mohave centered on death, namely the funeral and subsequent commemorative mourning ceremony. As soon as possible after death, the deceased was cremated upon a funeral pyre along with all of his or her possessions. The house and granary of the deceased were also burned. It was believed that by burning, these things would be transmitted to the land of the dead along with the soul of the deceased (Stewart 1983b, pp. 65–67).

Due to their relatively remote location inland, the Mohave maintained their independence throughout the Spanish period of the sixteenth and seventeenth centuries and were only rarely visited by explorers during that time. The few Spanish accounts of encounters with the Mohave provided similar descriptions of Mohave lifeways as those reported later by ethnographers. It is believed that the ancestors of the Mojave resided in the area for at least 1000 years and the mode of life in prehistoric times is thought to be similar to that observed historically (Stewart 1983b, p. 56).

The Maricopa and the Halchidhoma

Ethnographic information for the Maricopa and Halchidhoma is meager in comparison to the Mohave and the Quechan. The following brief summary is derived from Harwell and Kelly (1983) and Stewart (1983a).

The Halchidhoma first entered written history in the early seventeenth century with the account of Juan de Oñate, who encountered the "Alebdoma" or "Halchedoma" during a Spanish expedition on the lower Colorado River, below its junction with the Gila River. When later encountered by missionary-explorer Eusebio Francisco Kino in the early eighteenth century, the Halchidhoma (or "Alchedoma," as they were referred to by Kino) had moved farther north up the Colorado beyond the Gila. The traditional territory attributed to the Halchidhoma lay along the lower Colorado between the Mohave and the Quechan territories. They were later driven from that area under pressure from their hostile Mohave and Quechan neighbors and moved to the middle Gila River area, where some merged with the Maricopa (Stewart 1983a).

The term Maricopa refers to the Yuman-speaking groups who in the early nineteenth century occupied the area along or near the Gila River and its tributaries (in what is now

southern Arizona), but who earlier had occupied the lower Colorado River area. The Maricopa language is closely related to Quechan and Mohave, all three of which are classified as members of the River branch of the Yuman language family (Harwell and Kelly 1983, p. 71). The Maricopa call themselves pi•pa•s, “the people.” The name Maricopa is an English abbreviation of the name Cocomaricopa, first used by Eusebio Kino in the late seventeenth century (Harwell and Kelly 1983, p. 83).

The Maricopa, who by the early nineteenth century included remnant tribes of the Halyikwamai, Kahwan, Halchidhoma, and Kavelchadom, share common origins and are culturally similar to both the Quechan and the Mohave, the most prominent traits of which included floodwater agriculture and cremation of the dead. Their material culture was also essentially the same (Harwell and Kelly 1983, p. 71). The Colorado River Maricopa lived in low, rectangular, earth-covered houses, but the Maricopa of the Gila River had adopted the round houses of their Piman neighbors. Technology was of little interest to the River Yumans and remained at a low level of development (Stewart 1983a).

Historical Background

The RSEP is located in an area that has historically been and remains remote from centers of development and settlement. The primary historic themes in this discussion focus on Spanish and Mexican routes through the desert, early American traffic, mining, transportation, military training, power transmission, and agriculture/ranching.

Transportation

Spanish and Mexican Routes through the Desert

Sixteenth-century maritime Spanish explorer, Hernando de Alarcon, made the first Euroamerican incursion into the region in 1540, ascending 85 miles up the Colorado River to a point near present-day Yuma. Alarcon was sent to supply Coronado’s land expedition that had set out on foot from Compostela, Mexico, in search of the fabled seven cities of gold. He eventually cached the supplies and departed after waiting many days. Melchior Diaz, leading a small contingent of Coronado’s land unit, later arrived and recovered the supplies. Both Alarcon and Diaz noted the bleak nature of the country. The interior of the Colorado Desert was not explored further until 1702 when Father Eusebio Francisco Kino, a Jesuit missionary from Sonora, began seeking an overland route to coastal California (Rice et al. 1996; Hague 1976; Warren 1980, pp. 83–88).

Nearly seventy years later, Francisco Garcés (a Franciscan Padre) also seeking a route to the coast, forded the Colorado River at the mouth of the Gila River, and went west through the desert before turning back. His efforts were eventually rewarded in March 1774, when he arrived at Mission San Gabriel, accompanying the expedition of Captain Juan Bautista de Anza (Rice et al. 1996, Hague 1976). In 1779, two mission outposts were subsequently established near present-day Yuma to minister to the native Quechan, and strengthen Spain’s hold on this strategic point of entry into California. All passage along this route, later known as the Anza or Yuma Trail, was discontinued in 1781 when the Quechan revolted, killing over thirty missionaries, settlers, and soldiers, including Garcés.

Early American Trans-Desert Crossings

In 1846, during the opening stages of the Mexican-American war, General Stephen Watts Kearny led an advance column of the United States Army into the southern California desert. From Santa Fe, Kearny's troops entered California by way of Yuma, reaching San Diego in December, having abandoned their wagons shortly after crossing the Rio Grande. The war ended in 1848 with the signing of the Treaty of Guadalupe Hidalgo, ceding California and the adjacent Southwest to the United States.

Only days after the Mexican-American War ended, gold was discovered in California, beginning the Gold Rush. It is estimated more than 100,000 travelers entered California by way of the Yuma Crossing.⁶ The presence of so many travelers along this route highly impacted the desert. Whereas previous expeditions made the journey in isolation, during the Gold Rush, trails became de facto highways. Companies of miners frequently encountered one another, or encountered recently vacated campsites. The desert floor also became littered with articles abandoned when they either fell apart or proved too heavy or cumbersome for transport. Broken wagons, furniture, articles of clothing, tools and even weapons left by the side of the road became a bonanza for scavengers (Lamb n.d.).

After 1851, travel to California along the southern route through the Colorado Desert declined (Lamb n.d.). Horse traders and livestock drovers still used the trail to drive herds from Texas and Mexico to California, and the U.S. Army continued to send caravans of provisions from San Diego to its outpost Fort Yuma, at least until 1852. Emigrants, moving west, however, were more apt to be settling in Southern California as farmers or ranchers rather than prospecting for mineral resources.

The Weaver Route/Trail

Sometime during the 1850s, Pauline Weaver, a mountain man, scout, rancher, and miner, blazed a trail across the desert to the Colorado River. The route appears to have passed by Rice (von Till Warren and Roske 1981, p. 20), following in part the route of current Highway 62. Weaver kept his route a secret, and it was little used. He may have been shown the route by local Native Americans whom he had lived among.

Automobile Roads

Automobiles began replacing buckboards (four-wheeled wagons drawn by a horses or mules) about 1910.⁷ Because of bad roads, the high-centered Model-T was the vehicle of choice. At that time, no maps, road signs, or service stations existed. Venturesome motorists in Southern California, faced with these circumstances, banded together in 1900 to form a touring club, and began publishing a monthly magazine with tips on travel and directions to popular destinations (Warren 1980, p. 92). Because desert driving could be perilous, motorists began advocating for better information and road assistance. In 1917, the U.S. Geological Survey erected signs directing travelers to water at 167 localities in California's desert (Thompson 1921).

⁶ <http://www.yumaheritage.com/history.html>

⁷ <http://www.dustyway.com/2008/12/desert-driving-in-early-days.html>

The California Department of Engineering, after paving its first auto road in 1912, began issuing maps in 1918 (Warren 1980, p. 92). Roads remained unpaved for the most part through the 1920 with the exception of a two-mile wood planked section between Brown's Well and Blythe Junction (Brown 1920, pp. 64-65, fig. 1; 1923, pp. 180-181, fig 11). A decade later, during the construction of the Colorado River Aqueduct, Parker Dam Road (renamed California State Route 62 in 1970) became part of the paved road network (Metropolitan Water District 1941, p. 25). This road runs along the northern boundary of the Project.

Railroads

Many rail lines cross the Mojave and Sonora Deserts including the Union Pacific, the Central Pacific (CP), the Southern Pacific (SP), and the Atchison, Topeka, and Santa Fe (ATSF). Of these railroads, lines formerly part of the ATSF run parallel to and north of the RSEP ownership property. The ATSF was initially established in 1860 to run from Atchison and Topeka, Kansas to Santa Fe, New Mexico (Bryant 1974; Marshall 1945; Waters 1950). After completing this mainline segment, the railroad quickly expanded both east and west.

Between February 1882 and August 1883, the Atlantic and Pacific (AP) Railroad constructed a line between Mojave and Needles, California (Myrick 1963, pp. 762-793). Crossing the southern Mojave Desert, the railroad passed through Barstow, Ludlow, Amboy, Cadiz, and Goffs. From Needles the route proceeded east across north-central Arizona and New Mexico to Albuquerque, New Mexico. Operating control of the Mojave Desert portion of the line immediately passed to the SP.

The following year, an agreement was reached turning control of the AP over to the ATSF. During the rest of the 1880s, the ATSF expanded its presence in California, reaching San Diego and San Francisco. Needles and Mojave became important operational centers. Two decades later, ATSF recognized a need for a line from Phoenix into California (Bryant 1974, pp. 186-187; Marshall 1945:p. 183, pp. 267-268; Myrick 1963, p. 792; Waters 1950, pp. 357-358). Beginning in March 1904, construction began along the 100-plus miles across western Arizona. Progress was slowed by a shortage of workers who could withstand the heat. Parker was finally reached on June 17, 1907.

Construction of a bridge across the Colorado River was difficult, and was not completed until Summer 1908. The national recession (i.e., "panic") of 1907 further delayed construction of the 82-mile segment from Parker via Rice to Cadiz. It finally was completed on July 1, 1910. During 1916, the 41-mile Palo Verde branch line was built by the California Southern Railroad. It extended from Rice (originally known as Blythe Junction) south to Blythe.

Harnessing the Colorado - The Colorado River Aqueduct

The paucity of water in the Southern California desert made agriculture a challenge. Plans to improve matters began as early as the 1880s. Thomas Blythe, an investor from San Francisco, backed construction of a canal in the Palo Verde Valley,⁸ 65-miles south

⁸ <http://www.pvid.org/History.html>

of the RSEP. Water, taken from a swamp area called Olive Lake, was used to irrigate pasturelands and small agricultural plots. With Blythe's death in 1883, no further agricultural development in the valley occurred, until the turn of the century. In 1904, the Palo Verde Land and Water Company purchased the Blythe Estate, and began constructing additional canals and intake structures. Two years later, the California state legislature was petitioned to pass the Palo Verde Irrigation District Act to better administer irrigation and drainage.

The Colorado River Aqueduct, which runs immediately north of Rice, was part of a series of 20th century projects designed to utilize water from the Colorado River for agricultural and urban development. Although schemes to appropriate Colorado River waters began as early as 1859, it was not until the first decade of the 20th century that a significant effort was made to harness the Colorado (Starr 1990, Chapter 2; Stevens 1988, pp. 10-16). Private developers formed the California Development Company, and dug a canal to convey Colorado River water to irrigate farms in the Imperial Valley. Following completion of the canal in May 1901, over 10,000 people came to the Imperial Valley during the next three years. Problems with silting and seasonal water supplies led to construction of a new canal without a headgate in 1904.

Disaster struck in Spring 1905 when a series of Colorado River floods overwhelmed the canal. The river began cutting a new channel into the Imperial Valley, with its waters forming the Salton Sea. When efforts to return the Colorado to its original course failed, the California Development Company turned to the Southern Pacific Corporation for financial and engineering assistance in June 1905. After spending \$3.1 million, the SP finally returned the river to its former course in February 1907.

Following the 1905-1907 disaster, continuing problems with siltation, floods, and seasonal lack of water plagued Imperial Valley farmers. During the 1910s, it was increasingly evident that a dam(s) on the Colorado was needed to control flooding and provide dependable water storage, along with construction of a new water delivery system to the Imperial Valley (Hundley 2001, pp. 211-234; Starr 1996, Chapter 11; Stevens 1988).

In April 1922, the Swing-Johnson Bill for the Boulder (i.e., Black) Canyon Project was introduced in the U. S. Congress. A subsequent U.S. Supreme Court decision (*Wyoming vs. Colorado*) held that the doctrine of prior water appropriation governed water allotments from a shared water source to individual states. This produced immediate opposition to the Boulder Canyon Project by six of the seven states located within the Colorado River Basin, who feared that California would obtain most of the basin's water as a consequence of the court decision.

In November 1922, U.S. Secretary of Commerce Herbert Hoover presided over a conference attended by representatives from the seven Colorado Basin states. The resultant Colorado River Compact established formulas for sharing and distributing Colorado River water and hydroelectric power. After several years of political maneuvering by basin states and further amendments, the terms of the compact were approved by six states, and ratified by Congress. In December 1928, Congress passed the Boulder Canyon Project bill.

One of the first acts of Herbert Hoover's presidency in early 1929 was to authorize the Boulder Canyon Project to proceed. In March 1931, the \$48 million construction contract was awarded to the Six Companies. With Frank Crowe as construction supervisor, work on Hoover Dam immediately began. Dedicated at the end of September 1935, the dam provided a massive storage facility for Colorado River water in Lake Mead, effectively ending downstream flooding, and ensuring a year-round water supply.

William Mulholland, anticipating the high demand for water in Southern California, began sending survey crews into the desert in 1923 to find an aqueduct route to transport water from the Colorado River to the coastal plain (Hundley 2001; Metropolitan Water District 1941; Mulholland 2001; Starr 1996, Chapter 11). In 1928, fearing droughts and future water shortages, 13 Southern California cities (Los Angeles, Burbank, Glendale, Pasadena, San Marino, Beverley Hills, Santa Monica, Torrance, Compton, Long Beach, Fullerton, Anaheim, and Santa Ana) formed the Metropolitan Water District of Southern California (MWD). During November-December 1930, the Parker route for the aqueduct was adopted. On September 29, 1931, by a five-to-one margin, MWD voters approved a \$220 million bond issue to construct the Colorado River Aqueduct.

Construction was completed on October 14, 1939. The first water reached Southern California's coastal plain in June 1941. The aqueduct is recognized as one of the engineering marvels of the modern world, and was nominated as a National Historic Engineering Landmark by the American Society of Civil Engineers.^{9,10} It involved the labors of an estimated 35,000 people.

A portion of this aqueduct runs along the northern edge of the RSEP ownership property. It is a concrete-lined canal, 20-55,12 feet wide and 11,71 feet deep (Metropolitan Water District 1941, pp. 36-37 (map), 39). The Colorado River Aqueduct was constructed between 1933 and 1941 (Hundley 2001, pp. 227-234; Metropolitan Water District 1941; Starr 1996, Chapter 11). It runs 242 miles from Lake Havasu on the Colorado River to Lake Matthews in western Riverside County, using five pumping plants, 92 miles of tunnels, 63 miles of concrete-lined canals, 55 miles of concrete conduits, and 144 siphons, totaling 29 miles. Parker Dam, impounding Lake Havasu on the Colorado River was built between 1934 and 1938 (Hundley 2001, pp. 229-230; Reisner 1993, pp. 257-259).

⁹ <http://www.mwdh2o.com/mwdh2o/pages/about/history4.swf>

¹⁰ The Los Angeles Aqueduct, which conveys water 238 miles from the Owens River on the east side of the Sierra Nevada Mountains, was mastermind of William Mulholland and his associates. Their deceptive tactics were used to obtain Bureau of Reclamation water rights and subsequently secure a bilateral monopoly of one buyer and one seller (the Los Angeles Water Board and the Owens Valley Irrigation District). Construction began in 1908 and was completed in 1913.

Mining

Riverside County is known mostly for sporadic, small-scale mining of gold, silver, lead, copper, uranium, fluorite, and manganese. Shumway et al. (1980), provide an overview of mining in region, focusing on areas adjacent to the project area. Large numbers of prospectors were attracted to the region during the gold boom in La Paz, located in western Arizona approximately six miles north of present day Ehrenberg, in 1862. During 1865, the Mule Mountains, approximately 90 miles south from the project area, became the first discovery of gold in Riverside County. Not long after, miners began prospecting in the mountains located on either side of the Rice Valley. As early as 1865, iron ore was being mined in the Eagle Mountain District southwest of the RSEP.

The RSEP project area is surrounded by a number of mining districts. They include the Arrow (90 miles northwest of the project), Freeman (located 40 miles northwest of Project Area from the Old Woman Mountains east to the Chemehuevi Mountains), Chemehuevi (northeast of Project Area, approximately 30 miles, within the Whipple Mountains), Copper Basin (also located in the Whipple Mountains), and Sunrise (roughly 15 miles north in the Turtle Mountains) Districts (Shumway et al. 1980). In addition, several local mountain ranges also have produced significant commodities, including the Arica and Little Maria mountains.

The Arica Mountains, roughly 5 miles southwest of the RSEP was heavily mined for gold and copper, along with small amounts of lead, silver, and iron. Lum Gray and John L. Thomas Brown were the first prospectors in the area, and discovered gold in 1894. Lum went on to develop the Onward Claim with this brother (Shumway et al. 1981). By 1912, this area was known as the Arica group of claims,¹¹ and was operated by Lum's son, Jack Gray. In March 1913, the mines were leased to J.V. Priest, of Assets Realizing Mines Company, who set up a mill, and pumped water from Brown's Well three miles away. The mines continued to change hands over the years, and experienced limited periods of operation.

Rock salt was mined at Danby Lake, 15 miles to the west/northwest (Bailey and Aubury 1902; Ver Planck 1958). From 1890 to 1894, one of the earliest rock salt mining operations in California was conducted by the Crystal Salt Company, which had prospected in 1882. Most of the salt was shipped to mines at Calico by steam traction wagons. Subsequent mining occurred on a smaller scale during World War I, the 1920s, and from 1934 to 1942. In addition, sizeable sustained gypsum mining began in the early 1920s in and around Midland, 15 miles due south of the project area, in the Little Maria Mountains (Murdoch and Webb 1956; <http://vredenburgh.org>). A railroad from the Palo Verde Valley to Rice (formerly Blythe Junction) and south to Midland was eventually built by 1916 to import supplies and export gypsum.

A review of the BLM's National Integrated Land System (NILS) GeoCommunicator website,¹² shows that the majority of the RSEP project area lacks prior disturbance by mining activities. Some mining may have occurred along the western boundary of the RSEP ownership property (mostly mining associated with the Arica Mountains).

¹¹ Other mines in the area include: Brown Mine North, Brown Mine, Mountain Queen, Randolph and Hamilton, and other unnamed prospects.

¹² <http://www.geocommunicator.gov/GeoComm/index.shtml>

Former Community of Rice

Rice, originally named Blyth Junction, was a small community, adjacent to a subdivision and siding on the AP/ATSF Railroad (Brown 1920, pp. 64-65, fig. 1; 1923, pp. 180-181, fig. 11). A well, which ultimately was abandoned, was driven to 355 feet to provide water for railroad locomotives (Brown 1923, pp. 88-101). In the late 1910s-early 1920s, the community had a post office, Blythe Junction, open from November 5, 1910 to September 30, 1916 (Frickstad 1955, pp. 138), and provided water, meals, and sometimes gasoline and general supplies to desert travelers (Thompson 1921, pp. 223-225). During the mid-1930s, Rice had about 15 inhabitants, and a two-pump Shell gasoline station run by the Weaver Family. The Rice Post Office was open between March 1, 1933 and May 31, 1943, and was reestablished on July 1, 1946, closing again at a later date sometime after 1955 (Frickstad 1955, pp. 145).

A Union 76 service station, now in ruins, was open until the late 1970s. Currently, Rice is a vacant site with no standing structures or residents. Along the right-of-way of the Arizona and California Railroad (formerly the ATSF), travelers along Highway 62 have spelled out their names and other forms of graffiti with ballast stones taken from the railroad grade.

Military Activities

19th Century- Camp Cady

With the increase in traffic along southern California desert routes, the U.S. government thought it necessary to establish military outposts to protect travelers from Native American attacks. Major facilities were established at Fort Yuma from 1850-1883, Fort Mojave (1859-1890), and Camp Cady between, 1860 to 1871 (Hart 1965, pp. 57-60, 112-115, 124-126; Ruhge 2005, pp. 408-411, 445-447, 470-475; Waitman 1954, 1968).

By order of General N.S. Clarke, Camp Cady was established on April 14, 1860, roughly 130 miles northwest of Rice Army Air Field. This camp was not intended to be permanent, and therefore, Major Carleton only constructed temporary shelters made of grasses for his men. Carlton subsequently established Fort Beale as a subpost of Camp Cady. This installation was located about 10 miles north of Goffs.

Camp Cady was officially re-activated on April 23, 1865, housing Company C, 4th California Volunteer Infantry for a little over a year until July 6, 1866. Before this time, the only "structures" at the camp were hastily made brush shelters. After 1866, permission was received to construct 35 adobe buildings (Hart 2009). Despite this, the government attempted to close the camp during the same year, but public pressure for continued military protection was too strong. Later in 1866, five soldiers were killed. Threats to the area required continual patrols and wagon train escorts increasing the number of soldiers in the camp to 120 men.

Eventually the need for Camp Cady was less important, and it was moved one-half mile west in 1868 to a location with sufficient area for a parade ground, which was not possible at its former site. In 1868, the number of troops was cut in half as safer, more efficient, travel routes were established elsewhere. Finally in 1871, the camp's buildings were sold to civilians, and used by missionaries.

20th Century Military Activities

The Desert Training Center

In 1942, during World War II, General George S. Patton established the Desert Training Center/California-Arizona Maneuver Area (DTC/C-AMA) in a sparsely populated region located in southeastern California, Arizona, and Nevada. Its purpose was to prepare tank, infantry, and air units for the harsh conditions of North Africa by practicing maneuvers, developing tactics, and field testing equipment (Bischoff 2000; Crossley 1997; Howard 1985; Meller 1946). The installation, operated for two years, was originally 10,000 square miles in extent, reaching 28,000 square miles by mid-1943 (Crossley 1997). The facility was the first simulated theater of operations in the United States. Its location was chosen for its unforgiving desert heat, rugged terrain, telephone communications system, accessibility by established railroads and highways, and its proximity to the Colorado River Aqueduct that ensured a reliable water supply (Bischoff 2000; Crossley 1997; Henley 1992, pp. 5–7; Howard 1985, pp. 273–274).

A number of military camps were established in California, Nevada, and Arizona (Bischoff 2000; Crossley 1997; USACCE 1993). California installations included Camps Clipper/Essix, Coxcomb, Desert Center, Goffs, Granite, Iron Mountain, Ibis, Ono, Pilot Knob, Rice, and Young. Camp Young, near Indio, served as the main headquarters, activated on April 28, 1942. Army Air Fields were established at Blythe, Desert Center, Rice, Shavers, and Thermal. Between 1942 and 1944, 20 divisions, 13 infantry and 7 armored, participated in maneuvers at the Desert Training Center. With the exception of one National Guard division, all were Regular Army formations (Crossley 1997). Training followed an eight-week regimen.

Throughout its existence the Desert Training Center, renamed the California-Arizona Maneuver Area in October 1943, experienced logistical problems with obtaining supplies and transporting troops, compounded by a chronic lack of service units. As a result, the War Department closed the facility in April 1944, turning it over to the 9th Service Command which policed the area, closed the camps, and collected/salvaged all equipment and materials. Following the end of World War II, little was left of the post's facilities, except foundations, road grids, and other features.

Camp Rice

Camp Rice was a divisional camp of the DTC/C-AMA, located three miles east of the community of Rice, California, immediately adjacent to Rice Army Air Field (AAF). As with all divisional camps, Camp Rice was constructed as a temporary facility to create a realistic wartime conditions training atmosphere for stationed military personnel. Built during early 1942, the camp housed the 5th Armored Division from August to October 1942. Men of the 6th Armored Division resided there from November 1942 to March 1943 (Bischoff 2000, p. 84). Training included field exercises such as night movements use of firing ranges, anti-aircraft firing, and training with anti-tank weaponry (Meller 1946, p. 60). The 6th Armored participated in training exercises with the 4th Armored in early 1943. Shortly following this exercise, the division was moved to Camp Coxcomb, located southwest of Camp Rice. This facility had better amenities for the troops (Fergusson and Calvit 2009, p. 2-12).

Rice Army Air Field

Rice Field pre-dated World War II. It began as a municipal airport for the community of Rice constructed sometime after 1932 (Freeman 2010). A decade later, the airport was acquired by the 4th Air Support command and was in military use by October 26, 1942. As part of the combat training, the Army Air Force and the Army Service Force were included, serving as support to Army Ground Forces (AGF).

Air squadrons were primarily assigned supporting roles to the ground units, providing tactical support and generally creating a realistic combat environment (Blake, 1996). During maneuvers and other training operations, planes flew low over the troops in order to prepare them for strafing in actual combat. Air crews also practiced bombing and gunnery on several ranges spaced throughout the DTC/CAMA. For the most part, air-to-ground gunnery practice was focused on the toes of nearby mountains (Hazenbush, 1944).

A variety of airplanes were used. L-1 and L-4 Piper Cubs were common for surveillance, proving invaluable in spotting enemy units and directing artillery fire more effectively. Low flying, twin-engine A-20 Havoc attack airplanes (light bombers) were perhaps the most frequently encountered by ground troops. Because of the presence of these aircraft, small units learned the importance of camouflage, dispersion, and the digging of slit trenches. In several instances, C-50 cargo planes were used to supply troops during maneuvers. Douglas C-47, P-39 Airacobra, P-40 Warhawk, and P-38 Lightning were also known to have been used at the DTC/CAMA.

The Rice AAF had two 5,000-foot runways and numerous dispersal pads. The airfield contained barracks, recreation and mess halls, powerhouses, and support facilities to house 3,000 men. By 1943, 4,000 men were reportedly stationed there (Bischoff 2000, p. 93; Fergusson and Calvit 2009, p. 2-10). The 836th Engineer Aviation Battalion was temporarily stationed in adjacent Camp Rice to assist in construction/improvement of the airfield before being moved to Camp Young which had better amenities.

After the DTC/C-AMA was closed on April 30, 1944, Rice AAF was assigned to March Field as a sub-base. It ceased operating on August 2, 1944. In 1949, the field was reopened as a civilian airport. The air field was privately owned from 1951 through 1955. Its final abandonment occurred sometime between 1955 and 1958 (Freeman 2010).

Operation Desert Strike

During the Cold War years, relations between the United States and the Soviet Union were fragile. While a campaign promoting the nonproliferation of nuclear weapons began in 1958, a treaty was not signed until 1970. Amid worries of nuclear war, a two-week training exercise occurred in 1964 called Desert Strike. It involved over 100,000 men, 780 aircraft, 1,000 tanks, and 7,000 other vehicles ranging over 150,000 square miles in California, Nevada, and Arizona, along the banks the Colorado River and adjoining desert valleys (Garthoff 2001, p. 199; Nystrom 2003). Four Army divisions, three Army Reserve and National Guard brigades, and fifteen tactical Air Force squadrons participated in the exercise.

The exercise was a two-sided enactment, with fictitious world powers “Calonia” and “Nezona” sharing a common border along the Colorado River. The premise of the conflict between these two entities, each led by a Joint Task Force, was a dispute over water rights. Major tactical operations during the exercise included deep armor thrusts, defensive operations along natural barriers, counterattacks including airmobile and airborne assaults, and the simulated use of nuclear weapons. The Air Force provided fighter, air defense, interdiction, counterair reconnaissance, and troop carrier operations in support of both joint task forces (Desert Strike n.d., p. 316).

In the first phase of Desert Strike, Calonia initiated mock battle with a full-scale invasion of Nezona. A new technique for military river crossings was put into operation during this invasion. It was accomplished with a combination of assault boats, amphibious armored personnel carriers, ferries, bridges, and fords at eight major sites across a 140-mile long stretch of the Colorado River. Attack and counterattack continued into a second phase during which simulated nuclear strikes and airborne assaults occurred. Heavy equipment, such as M60 tanks, was used during the maneuvers, and their track marks can still be seen across the desert (Prose and Wilshire 2000).

CULTURAL RESOURCES INVENTORY

A project-specific cultural resources inventory is a necessary step in staff’s effort to determine whether the proposed project may cause significant impacts to historically significant cultural resources and would therefore have an adverse effect on the environment.

The development of a cultural resources inventory entails working through a sequence of investigatory phases. Generally the research process proceeds from the known to the unknown. These phases typically involve doing background research to identify known cultural resources, conducting fieldwork to collect requisite primary data on not-yet-identified cultural resources within and near the proposed project, assessing the results of any geoarchaeological studies or environmental assessments completed for the proposed project site, and compiling recommendations or determinations of historical significance for any cultural resources that are identified.

This subsection describes the research methods used by the applicant and Energy Commission staff for each phase and provides the results of the research, including literature and records searches (California Historical Resources Information System (CHRIS) and local records), archival research, Native American consultation, and field investigations. It also provides a brief description of cultural resource types identified by the applicant. Thus, the inventory consists of the body of resources the applicant identified in the AFC, and the descriptions are limited to what the applicant provided, either with the AFC or in response to staff’s data requests. Staff’s assessments of project’s impacts are presented in a separate subsection below.

Area of Potential Effects

The concept and general definition of the Area of Potential Effects (APE), similar to the CEQA project area for the purpose of analysis, are discussed under “Methodology and Thresholds for Determining Environmental Consequences. Archaeological and built-

environment APEs are defined below for the RSEP, considering both the horizontal and vertical dimensions (above and below ground) of the project.

Archaeological APE

For archaeological resources, staff has defined the horizontal extent of the APE to include the project ownership property; the CEC mandated minimum 200-foot buffer around the ownership property, the approximately 10-mile long generator tie-line with an associated 100-foot buffer, substation with a 100-foot buffer, and the fiber optic telecommunications line that will replace the existing ground wire along the Parker-Blythe No. 2 - 161kV Transmission Line. Following these CEC mandates, the RSEP horizontal archaeological APE encompasses a total of 4,002-acres (3,772.8 for the ownership property/generator tie-line/switchyard and 228.9 for the buffer area) and 2,291 acres for the fiber optic overhead groundwire replacement (764 acres in the existing right-of-way and 1,527 acres for the buffer area).

The archaeological APE is located on the following USGS 7.5-Minute Quadrangles: *Big Maria Mountains NW, California* (1971), *Grommet, California* (1971), and *Rice, California* (1983), *Gene Wash, California-Arizona* (1959), *Cross Roads, California-Arizona* (1977), *Parker, Arizona-California* (1975) , *Parker NW., California* (1975), *Parker SW., California-Arizona* (1975), *Vidal, California* (1975), *Big Maria Mountains SW, California* (1972), *Mc Coy Wash, California* (1975), and *Ripley, California* (1975).

The study area is located in portions of the following survey sections: Township 1 South, Range 20 East: Sections 24 and 25; Township 1 South, Range 21 East: Sections 19, 20, 29, 30, 33, 34, and 35; Township 2 South, Range 21 East: Sections 1 and 2; Township 2 South, Range 22 East: Sections 6 (presumed), 7, 8, 16, 17, 21, and 22); Township 2 North, Range 27 East: Sections 4, 5, 8, 17, and 18; Township 2 North, Range 26 East: Sections 13 and 24; Township 2 North, Range 26 East: Sections 22, 23, 24, 27, and 28; Township 2 North, Range 26 East, Sections: 28, 31, 32, 33; Township 1 North, Range 26 East, Section: 6; Township 1 North, Range 25 East, Section: 1, 10, 11, 12, 15, 16, 17 (presumed), 20 (presumed); Township 1 North, Range 25 East: Sections 19 (presumed), 20 (presumed), and 30 (presumed); Township 1 North, Range 24 East: Sections. 25, 26, 33, 34, and 35; Township 1 South, Range 24 East: Sections 4, 5, 6, and 7; Township 1 South, Range 23 East: Sections 12, 13, 14, 15, 21, 22, 29, 31, and 32; Township 2 South, Range 23 East: Section 6 (presumed); Township 2 South, Range 22 East: Section 1 (presumed), Township 2 South, Range 22 East: Sections 1 (presumed), 2 (presumed), 11 (presumed), and 14 (presumed); Township 2 South, Range 22 East: Sections 14 (presumed), 15 (presumed), 22 (presumed), 27 (presumed), 33 (presumed), and 34 (presumed); Township 3 South, Range 22 East: Sections 4, 8, 9, 17, 20 (presumed), and 29 (presumed); Township 3 South, Range 22 East: Section 32 (presumed); Township 4 South, Range 22 East: Sections 5 (presumed), 6 (presumed), 7 (presumed), 18 (presumed), 19 (presumed), 30 (presumed), and 31 (presumed); Township 5 South, Range 22 East: Sections 5 (presumed), 6 (presumed), 7 (presumed), and 8 (presumed); Township 5 South, Range 22 East: Sections 8, 17, 20, 29, 32, and 33; Township 6 South, Range 22 East, Sections 4, 9, 16, 21, and 28; Township 6 South, Range 22 East: Sections 29 and 33.

The archaeological APE also includes a vertical dimension determined based on the maximum depth that would be reached by all foundation excavations and pipeline trenches. At the time of the submitted AFC, the structures included in the RSEP proposal include pipe racks, a turbine, water tanks, a liquid salt tank, heliostats, and the central tower/receiver. The maximum depth (below finished grade) for these structures is roughly 20 feet and the minimum depth (below finished grade) is 12-inches. At the time of these plans, a grading strategy had not been put into effect – to date, cut and fill depths, at various locations across the site, are presumed to be between 0 and 8 feet. The previously mentioned structures will have vertical heights and depths as follows: turbine with a mat foundation¹³ and height of 8 feet; water tanks with a 2-foot deep foundation and height of 30-feet; two liquid salt tanks also with a 2-foot deep foundation and height of 40-feet; the heliostat foundations may reach a depth of 10 to 12 feet and 33 inches diameter and a height above ground of 28 feet); and the central tower which will be situated on a donut shaped foundation with a height of 538-feet. The donut foundation (diameter of 115-feet) will have a central (immediately beneath the tower) depth of 20-feet and will thin out as it moves farther away from the middle, reaching a depth of 8 feet. If the fiber optics line is installed to replace the existing overhead ground wire the Parker-Blythe Transmission Line #2, it would be hung at a height of 60-70 feet, at the top of the H-frame wood pole structures.

Built-Environment APE

For built-environment resources, staff has defined the horizontal extent of the APE to include the project footprint and a surrounding half-mile buffer.

Ethnographic APE

For this project, staff identified no ethnographic resources and so defined no APE for them.

Background Inventory Research

Various repositories in California hold compilations of information on the locations and descriptions of cultural resources older than 45 years that have been identified and recorded in past cultural resources surveys. Applicants acquire information specific to the vicinity of their project from certain repositories and to provide it to staff as part of the AFC submitted to the Energy Commission. Additionally, to acquire further information on potential cultural resources in the vicinity of a proposed project, the applicant is required to make inquiries of knowledgeable individuals in local agencies and organizations and to consult Native Americans who have expressed an interest in being informed about development projects in areas to which they have traditional ties.

CHRIS Records Search

The California Historical Resources Information System, or CHRIS, is a federation of eleven independent cultural resources data repositories overseen by the California State Office of Historic Preservation. These centers are located around the state, and

¹³ In areas where shallow or mat foundations are planned and the existing grades are more than one-foot below the bottom of the footing, the upper \pm 2-feet of existing soils should be over-excavated to expose firm, native soils, prior to placement of engineered fill.

each holds information about the cultural resources of several surrounding counties. Qualified cultural resources specialists obtain data on known resources from these centers and in turn submit new data from their ongoing research to the centers. The Project falls within the jurisdiction of the Eastern Information Center, which is housed in the Anthropology Department at the University of California, Riverside.

Rice Solar's cultural resources consultant, CH2MHILL, conducted a records search at the Eastern Information Center, University of California, Riverside and at the San Bernardino Archaeological Information Center on April 23, 2009. This study area included the project ownership property and 1-mile buffer. A 0.5-mile buffer was established around the generator tie-line.

Previous Surveys

Seven previous studies have been conducted within the 1-mile radius of the Project, three of which lie within the proposed RSEP archaeological APE (Ri-1690; Ri-7753; Sb-5332). Ri-1690 was a linear survey (for a seismic testing line in 1983) that crossed the RSEP ownership property in the southeast corner. Ri-7753 was a survey for the Parker-Blythe Transmission Line No. 2. Sb-5332 was conducted in the northeastern corner of the RSEP area (at the location of existing telecommunications towers); resources were identified. Two of the remaining studies (Ri-1210 and Ri-7172) were block surveys of varying sizes located outside of the project area, but within the 1-mile search radius. The Tennessee Valley Authority conducted Ri-1210, located north of the generator tie-line, roughly 1.7-miles northwest of the generator tie-in's southeastern terminus, to survey two uranium exploration sites. Ri-7172 was a small study conducted for the implementation of telecommunications equipments near existing towers. The two remaining reports, Ri-1211 and Ri-1244, consist of overview studies for Rice Valley and the surrounding areas.

Cultural Resources Table 2
Previous Surveys within the Study Area (Records Search Limits)

Report No.	Date	Within APE	Author(s)	Title
RI-7172 (25006A)	2003	N	Pletka	Cultural Resource Assessment for the AT&T Wireless Services Facility No. 25006A, Unincorporated Riverside County, California

RI-1210	1981	N	Lippencott	A Cultural Resources Survey of Two Proposed Uranium Exploration Sites in Rice Valley, Riverside County, California
RI-7753	1998	Y	Schaefer	A Cultural Resources Inventory and Evaluation of the Parker-Blythe 161 kV Transmission Line No. 2, Riverside and San Bernardino Counties, California
RI-1211	1980	Y	Von Till Warren et al.	A Cultural Resources Overview of the Colorado Desert Planning Units
RI-1244	1978	N	BLM	Planning Unit Archaeological Survey Sample Unit Records
SB-5332	1999	Y	Duke	Cultural Resources Assessment for Pacific Bell Mobile Services Facility CM-688-01, County of San Bernardino, California

Previously Recorded Resources

The records search identified 81 previously recorded resources (64 prehistoric and 17 historical) within the RSEP study area, the vast majority of which are situated along the existing Parker -Blythe Transmission Line No. 2 (Cultural Resources Table 3 – Appendix A). Of these, 77 are located within the archaeological APE. The prehistoric sites include 29 trail segments (two with associated petroglyphs, several with associated lithic scatters and/or quarries), 26 lithic scatters, 7 quarry sites, one geoglyph, and one ceramic scatter. The historical sites include 3 small unnamed temporary Desert Training Center camp sites, Camp Rice, 2 mining camps, two historic roads, the Atchison-Topeka-Santa Fe Railroad, the Colorado River Aqueduct, the structural remains of a former Vidal power substation, and 6 refuse scatters and/or dumps.

Archival and Library Research

Detailed resource-specific information needed by staff may entail primary and secondary research in various archives and libraries. The applicant may include archival information as part of the information provided to staff in the AFC or may undertake such research to respond to staff's data requests. Staff may also undertake such research to supplement information provided by the applicant.

As such, CH2MHILL also visited the General Patton Memorial Museum (on July 30,

2009) in order to learn more about regional history¹⁴. CH2MHILL also performed other archival research including the examination of historic topographic maps including: several iterations of *Rice, California* (War Department 1:62,000 scale, 1943; War Department 1:62,500 scale, 1943; USGS 1:62,500 scale, 1954; USGS 1:34,000 scale, 1977) and *Big Maria Mountains* (USGS 1:62,500 scale, 1951). In addition, other historic maps were referenced online from California State University, Chico and University of Alabama. Also reviewed were maps from the Malcolm Rogers collection on file at the Museum of Man in San Diego.

Staff executed additional archival research, visiting the University of California, Davis Shield Library and conducted additional online searches for historic maps depicting the project area. The following maps were examined:

- Beale (1861), Map of Public Surveys in California, Scale 1:1,140,000.
- American Photo-Lithographic Company (1865), California, Scale 1:5,069,000.
- Asher and Adams (1872), California and Nevada- South Portion, Scale 1:1,267,000.
- Williams (1873), Map of California and Nevada, Scale 1:3,485,000.
- Colton (1873), Colton's California and Nevada, Scale 1:2,091,000.
- Mitchell (1875), Map of the State of California, Scale 1:2,408,000.
- Hardesty (1882), Map of California and Nevada, Scale 1:2,000,000;
- Hardesty (1883), Map of Southeastern California, Scale 1:1,140,000.
- Rand McNalley (1884), California, Scale 1:2,028,000.
- Punnett Brothers (1897), Map of the State of California, Scale 1:2,218,000.
- Rand McNalley (1897), California, Scale 1:1,190,000.
- U.S. Geological Survey (1914), Lithologic Map of California, Scale 1:2,000,000.
- Smith (1916), Geological Map of the State of California, Scale 1:760,320.
- Executive Order 11652, Section 3(E) and 3(D) or (E) (1972), Arizona-California-Nevada Desert Training Center Maneuver Area, Sheet 5.
- U.S. Geological Survey (1978), Rice Quadrangle, Scale 1:24,000.
- War Department (1944), California, Scale 1:62:500.

Local Agency and Organization Consultation

California counties and cities may recognize particular cultural resources as locally historically important by ordinance, in general plans, or by maintaining specific lists. To facilitate the environmental review of their projects, applicants acquire information on locally recognized cultural resources specific to the vicinity of their project by consulting local planning agencies and local historical and archaeological societies.

CH2MHILL contacted various institutions requesting information for the ownership

¹⁴ The General Patton Museum is located at Chiriaco Summit near Desert Center and contains information about the Desert Training Facility and other military history related to the Project area.

property and surrounding area. The following institutions were contacted by formal letter (dated October 8, 2009) General Patton Memorial Museum and Riverside County Historical Society.

Local Agency and Organization Consultation Results

CH2MHILL received no responses from the various institutions contacted. As portions of the RSEP falls on BLM land, a Fieldwork Authorization Request form was filed and approved. Contact with the CEC is ongoing to coordinate of project activities.

Native American Consultation

The NAHC maintains two databases to assist cultural resources specialists in identifying cultural resources of concern to California Native Americans, referred to by staff as Native American ethnographic resources. The NAHC's Sacred Lands database has records for places and objects that Native Americans consider sacred or otherwise important, such as cemeteries and gathering places for traditional foods and materials.

The NAHC Contacts database has the names and contact information for individuals, representing a group or themselves, who have expressed an interest in being contacted about development projects in specified areas. Both applicants and staff request information from the NAHC on the presence of sacred lands in the vicinity of a proposed project and also request a list of Native Americans to whom inquiries will be made to identify both additional cultural resources and any concerns the Native Americans may have about a proposed project.

CH2MHILL contacted the NAHC on August 31, 2009, requesting a list of local Native Americans who might have concerns about the RSEP and a search of the Sacred Lands Files for any known resources that might be affected by project impacts. The NAHC responded on September 9, 2009, indicating that there were no known Native American cultural resources in the area and supplied CH2MHILL with a list of individuals representing local Native American communities. At the time of CH2MHILL's inquiry, the co-lead federal agencies (Western and BLM) had decided to conduct further consultation with the identified Native American tribes.

Steve Tromly of Western corresponded with local Native Americans by letters dated January 26, 2010 (initial consultation) and June 30, 2010 (project status up-date). Cultural Resources Table 4 provides a list of those contacted, their affiliations, and responses, if any. Among those contacted were individuals from the Ramona Band of Cahuilla Mission Indians, Twenty-Nine Palms Band of Mission Indians, the Chemehuevi Reservation, the Colorado River Indian Tribe Reservation, the AhaMaKav Cultural Society (Fort Mojave Indian Tribe), the Morongo Band of Mission Indians, the San Manuel Band of Mission Indians, and the Torres-Martinez Desert Cahuilla Indians. A tribal meeting and site visit was held on April 8, 2010, with representatives from three tribes (Fort Mojave, Fort Yuman-Quechan, and Twenty-Nine Palms Band) in attendance. These tribes expressed interest in conducting an ethnohistory study for the proposed project area. Western sent a Scope of Work for the study to the three tribes on April 12, 2010.

CULTURAL RESOURCES Table 4
Summary of Applicant's Native American Consultation*

Contact	Affiliation	Sent	Response
Joseph Hamilton	Ramona Band of Cahuilla Mission Indians	Letter	None to date
Darrell Mike	Twenty-Nine Palms Band of Mission Indians	Letter	None to date
Joseph R. Benitez	None provided by the NAHC	Letter	None to date
Charles Wood	Chemehuevi Reservation	Letter	None to date
Michael Tsosie	Colorado River Reservation Indian Tribes	Letter	None to date
Linda Otero	AhaMaKav Cultural Society, Fort Mojave Tribe	Letter	6/17/2010 – states that the tribe would like to stay involved with the progress of the RSEP
Michael Contreras	Moronggo Band of Mission Indians	Letter	None to date

Results of Inquiries Made to Native Americans

Western and CH2MHILL have received few comments to date. The Cultural Society director for the Fort Mojave Indian tribe requested continued consultation by e-mail on June 17, 2010. Consultation with the Tribes is ongoing.

Field Inventory Investigations

To facilitate the environmental review of their projects, CH2MHILL conducted surveys of the main project footprint (heliostat field) and gen-tie line (4,002 acres) to identify previously unrecorded cultural resources in both the archaeological and built environment APEs. The CH2MHILL survey included a pedestrian archaeological survey and a built-environment windshield survey. No survey of the Parker-Blythe Transmission Line No. 2 was conducted as it had been previously surveyed in 1997. The applicant also conducted a geoarchaeological study to determine the likelihood of encountering buried cultural deposits.

Results of Pedestrian Archaeological Survey

CH2MHILL performed the pedestrian survey of the RSEP between August 31 and September 16, 2009 (Fergusson and Calvit 2009). A four-member crew and one field director walked transects spaced no more than 15 meters. Identified sites (i.e., artifact groups of 5 or more items) were recorded, photographed and their positions determined with handheld global position system (GPS) unit. Isolates (i.e., artifact concentrations of 4 or less) were not recorded. Isolated features were recorded as sites. An arbitrary

distance of 50-meters between artifacts and features or a change in landform was used to create boundaries between individual sites.

Cultural Resources Identified

CH2MHILL survey team recorded two new resources: an historic road segment along the transmission generator tie-line, and the Rice Army Air Field (AAF). They also recorded features at the western periphery of previously recorded Camp Rice, producing a site record update. They found 141 archaeological features and 98 artifact concentrations associated with the RAAF/Camp Rice (Fergusson and Calvit 2009, pp. 5:1-9). Documentation consisted of a listing of features/concentrations, very brief descriptions, a map of their locations, and some photographs. Feature forms were prepared of a representative sample of the features/concentrations (23%) identified during the field survey to demonstrate their general nature with the intent of completing the full documentation as part of the mitigation measures. Information on these features and artifact concentrations are presented in Cultural Resources Tables 5 and 6.

Historic Features

Rice AAF/Camp Rice contain 141 features including: 18 debris features (burned & unburned, piled or placed in pits); 14 earthen features (emplacements, a firing butt, a mound, and berms); 52 pits (unlined, rock lined, wood lined); 5 trenches; 31 concrete slabs (remnants of structures within the RAAF including, but limited to, kitchens, bathhouses, lavatory, barracks/officer's quarters, dispensary, headquarters, enlisted mess hall, and airfield operations building); 12 stone features (rock piles, rock alignments, aerial markers); and 9 miscellaneous features such as a drain, sign bases, sidewalk, wells, and wooden posts) (Cultural Resources Table 5, Appendix A).

Historic Artifact Concentrations

Artifact concentrations associated with Rice AAF include 39 localities, all of which are either refuse scatters or burned debris dumps, composed primarily of fuel cans, miscellaneous metal, paint cans, and food/beverage cans (Cultural Resources Table 6). Of these 39 locations, 27 (70%) are located within the receiver tower area and the remaining 12 (30%) are within the ownership property block. Fifty-nine artifact concentrations were found associated with the western periphery of Camp Rice. The majority (n=41) are debris scatters primarily comprised of food cans (i.e., sanitary cans, hole-in-top cans, food bottles, and army ration cans), but also glass, and construction debris. The rest are burned debris dumps. All are located outside of the solar tower outline, but within the ownership property boundary. (See Cultural Resources Table 6, Appendix A).

Results of Geoarchaeological Investigations

Geoarchaeological monitoring of a geotechnical investigation within the RSEP APE took place August 5, 2009 (Terracon 2009). Excavations of two test trenches were observed by Dr. Geoff Spaulding for presence/absence of paleosols, archaeological artifacts, or other evidence of archaeological deposition. Each trench was excavated to a depth of roughly 10 feet (~3-meters). Strata and stratigraphic boundaries were then described, identified, and recorded for each trench. Two alluvial units, each possessing several horizons, were identified. Trench 1 provided the most complete stratigraphic sequence.

The upper portion of Trench 2 was apparently removed during grading/construction of the RAAF and replaced by 16 to 30 cm of recompacted fill and rubble. From these observations, Spaulding concluded that the Holocene (the last 10,000 years) is restricted to roughly the top 20 cm. He also regarded it unlikely that subsurface archaeological resources exist within the project area.

Results of Windshield Survey for Built-Environment Resources

The field survey for the built-environment APE was conducted congruently with the archaeological resources survey (August 31 – September 16, 2009) (CH2MHILL 2009 5.3b, pp. 5-7). The CEC mandates a minimum 0.5 mile radius from the plan site and generator tie-line. The only structures over 45 years of age within the vicinity of the RSEP site are State Route 62, the Colorado River Aqueduct, and the Atchison, Topeka, and Santa Fe Railroad, all of which have been previously recorded and are outside the APE. As Rice AAF and Camp Rice structures were dismantled when they were closed, the architectural survey instead relied heavily on the literature review and historic aerials in order to create a complete context for the area (CH2MHILL 2009 5.3b, pp. 5-7).

Summary of Identified Cultural Resources in the Archaeological APE

A total of 77 sites are present within the APE, including both *previously* recorded resources and *newly discovered* ones identified during field investigations (Cultural Resources Table 7). Two of the resources, the Rice AAF and Camp Rice, contained numerous features and artifact concentrations, including refuse scatters, pits, and rock alignments [Cultural Resources Table 6 (Appendix A) and Table 7(see below)].

**Cultural Resources Table 7

NRHP and CRHR Evaluations of Cultural Resources

Previously recorded and newly recorded resources are discussed below in separate subheadings, followed by discussions of two proposed cultural landscapes (the Desert Training Center and the Prehistoric Trails Network).

Previously Recorded Resources within the APE

All previously recorded resources along the existing Parker-Blythe Transmission Line No. 2 were evaluated by Schaefer et al. (1998). Their eligibility recommendations (eligible, not eligible, and indeterminate¹⁵) are assumed valid for the purposes of this Staff Assessment and are listed in Cultural Resources Table 9, Appendix A. It is acknowledged that these recommendations have not received concurrence from the Office of Historic Preservation. Of the 77 resources considered, 23 were recommended eligible for the NRHP, 35 were indeterminate (therefore possibly eligible), and 18 ineligible. The only other resource previously recorded within the APE (not recorded as part of the Parker-Blythe Transmission Line No. 2) is Camp Rice. It has not been evaluated.

Newly Recorded Resources

Two new resources were identified during the CH2MHill surveys of the RSEP heliostat field and gen-tie line: the historic Rice AAF and an unnamed, unimproved dirt road. In addition, new features and artifact concentrations, associated with the previously recorded Camp Rice, were also identified. The road, while still having physical integrity, does not appear to be significant, thus, for purposes of this analysis, is considered ineligible for both the NHRP and CRHR. Eligibility recommendations for Rice AAF and Camp Rice are discussed below.

Bischoff (2007), the Applicant's historian for RSEP, argues that the Rice AAF and Camp Rice should be considered eligible for listing in the NRHP, having sufficient integrity to reflect their important historical association with the DTC/C-AMA. He regards Rice AAF to be, by far, the best example of a DTC/C-AMA airfield. It was a multifaceted facility containing many important elements, still evidenced by elaborate, improved-surface runways, taxiways, dispersal pads, streets, rock-lined walkways associated with a tent area, and foundations for various temporary structures such as barracks, mess halls, kitchens, lavatories, bathhouses, operations, etc. Staff concurs with Bischoff's eligibility recommendations for both the Rice AAF and Camp Rice. These resources meet all NRHP Criteria A, B, C, and D (also CRHR Criteria 1-4). See next section, Desert Training Center Cultural Landscape, for discussion regarding each criterion, as the arguments for the specific facilities (Rice AAF and Camp Rice) and the DTC/C-AMA as a whole are similar.

Condition of certification **CUL-11** requires the creation of a Historic Interpretive Area, providing: (1) consistency with the requirements of the Warren-Alquist Act and (2) a portion of the mitigation for the loss of the majority of features associated with the Rice

¹⁵ Resources listed as indeterminate are either: (1) very large lithic scatters with chipping station complexes that extended beyond the project ROW, precluding ability to record in entirety or to properly consider the archaeological context; or (2) resources that had been previously recorded and could not be relocated in 1998, possibly because they were originally mismatched or destroyed in the interim.

AAF and impact to Camp Rice. The Historic Interpretive Area would be located along the west side of the project's secondary access (fire access road), adjacent to several remaining artifacts of the Rice AAF (e.g., stem wall foundations and rock-lined paths), which would become part of an interpretive path. All sensitive site information related to the Rice AAF would be documented (and curated, if appropriate) prior to completion of the interpretive area and public access. Location of the Historic Interpretive Area at a considerable distance from the remaining Camp Rice would help limit additional public impacts to the Camp's remaining features.

Desert Training Center Cultural Landscape (DTCCCL)

In 1986, the BLM planned to nominate each of the seven camps to the NRHP, to develop an interpretive program for the DTC/C-AMA, and to provide historical resources protection through designation as an Area of Critical Concern (ACEC) (Bischoff 2000, p. 134). Bischoff (2000, p.133; 2007, p.159-160), developing an historical context for the DTC/C-AMA, concluded it was a significant resource under all four criteria of the NRHP.

In a later publication, Bischoff (2007, p.159) argues that the DTC/C-AMA meets Criterion A being associated with events that made a significant contribution to the broad patterns of our history. The DTC/C-AMA was one of a kind in U.S. military history. It was here that the tactical, strategic, and logistical doctrines were developed and refined and subsequently applied overseas. More than one million men trained here, representing more than ten percent of those serving in the war. The training left a lasting impression on them. Undoubtedly, this training contributed to the fighting capabilities of U.S. soldiers in WWII.

Under Criterion B, Bischoff (2007, p.159) argues that the DTC/C-AMAA is also associated with the lives of persons significant to our past. In this case, he argues that several preeminent figures in the U.S. Army served there and helped shape the facility. General George S. Patton, one of the best-known military figures of the twentieth century, was instrumental in the development of the training center. Other famous military personages included General Walton Walker, General Terry Allen.

Under Criterion C, Bischoff (2007, p.160) argues that the DTC/C-AMA, with its unique layouts of camps and airfields, embodies a distinctive characteristic of a type, period, or method of construction.

Lastly, Bischoff (2007, p.160) argues that the archaeological resources (e.g., refuse deposits, the footprints of runways and landing strips, tank tracks, barracks foundations, foxholes, bivouacs), many of which have artifactual components, may yield information important to America's history of desert training during WWII, meeting Criterion D.

He recommends that the facility be nominated to the NRHP as a discontinuous district of clearly functionally- and temporally-related cultural resources. He further proposes that the facility be recorded as multiple properties consisting of contributing and noncontributing elements to the district. Consequently, the DTC/C-AMA can be thought of as an interconnected landscape of World War II training sites that are highly significant for their contributions to our understanding of how American soldiers were trained during World War II.

Energy Commission staff, Western, and BLM supports the designation of a noncontiguous cultural landscape (historic district) that incorporates historical archaeological sites associated with Gen. Patton's World War II DTC/C-AMA, to be known as the Desert Training Center Cultural Landscape (DTCCL). The NRHP guidance for districts and cultural landscapes requires identifying certain characteristics, including boundaries, one or more periods of significance, thematic associations, and property (resource) types. The boundaries of the DTCCL need to be refined, based on the historical record. The period of significance is 1942–1944. The thematic associations include the nation's preparation for World War II, U.S. Military Training, Gen. George S. Patton, Jr., and Gen. Walton Walker. The DTCCL site types include, but are not limited to depots, airfields, ranges, bivouacs, maneuver areas, camps, and hospitals.

Energy Commission staff, Western, and BLM recommend that DTCCL is eligible for listing on the NRHP under Criteria A through D (CRHR Criteria 1-4). The DTC/C-AMA was the largest and the only such military training facility in American military history. The training that took place here undoubtedly helped to win World War II. Contributors to this landscape associated with the RSEP include the following: Rice AAF, Camp Rice, two other small military training camp sites and a military refuse dump (Cultural Resources Table 10).

Prehistoric Trail Network Cultural Landscape (PTNCL)

Energy Commission staff, Western, and BLM supports the designation of a noncontiguous cultural landscape (historic district) that incorporates prehistoric archaeological sites associated with the Halchidhoma Trail (CA-Riv-0053T) referred to here as the Prehistoric Trails Network Cultural Landscape (PTNCL). This landscape consists of important destinations in the Colorado Desert near Blythe, California, the network of trails that tie them together, and the features and sites associated with the trails. The foundation of this cultural landscape is a core group of 224 sites originally recorded by McCarthy (1993) and those found during survey of the Parker Dam-Blythe Transmission Line No. 2. Those from the Parker Dam-Blythe Transmission Line are found primarily at the south end of the Whipple Mountains and are thought by Schaefer et al. (1998:90) to be associated with an important route from Parker to Needles that may have been part of the *keruk* trail system, citing Altschul and Ezzo (1994) and Stone (1991:82).

In the 1990s McCarthy (1993) and a group of volunteers recorded 20 km of the Halchidhoma Trail (CA-Riv-0053T) as it curves around the southern and western side of the McCoy Mountains leading from the Blythe Intaligos (geoglyphs) through the Chuckwalla Valley. They identified 224 trail-associated sites and subsidiary trails associated with the Halchidhoma Trail. McCarthy's report provides the basis for preliminary definitions of the boundaries, period of significance, thematic associations, and property types of the PTNCL.

The NRHP guidance for districts and cultural landscapes requires identifying certain characteristics, including boundaries, one or more periods of significance, thematic associations, and property (resource) types. The boundaries of the PTNCL need to be refined as additional pieces are identified, but in broad terms the boundary extends

along the length of the historically known route of the Halchidhoma Trail, from where it begins near Blythe at the Colorado River, continuing to the west through the Chuckwalla Valley towards modern Los Angeles, with a suggested width of 10 miles. The period of significance also needs to be refined, but it appears that the prehistoric trail systems of southern California were used for thousands of years. Therefore, as a preliminary measure, Energy Commission staff defines the period of significance as the entire prehistoric and early historic periods. The thematic associations currently include travel, trade, and ritual. Resource exploitation, particularly the collection of stone tool and ground stone raw materials, is also an important theme. The PTNCL site types are divided into three categories: destinations, trails, and trail-associated sites or features.¹⁶

Destinations primarily include water sources, but also include residential, religious, and resource-collection sites. Water-oriented destinations include natural features such as rivers, springs, lakes, rainwater tanks, as well as man-made wells. Residential sites include villages and camps with evidence of a full range of activities. Religious sites include geoglyphs and petroglyphs. The importance of particular destinations is indicated by the web of multiple trails that converge on certain places, often mountain passes or water sources.

Trails can either be created by the movement of traveling feet or formally constructed. They average 30 cm in width and can be traced for many km, interrupted only by gullies and washes. Trails are usually the shortest and most convenient routes from one point on the landscape to another.

Trail-associated sites or features could include: concentrations of ceramics/pot drops, cleared circles, rock rings, rock clusters, rock cairns, rock alignments, petroglyphs, and geoglyphs. When the trail itself is not preserved, its route can often be approximately traced by distinctive patterns of trail-associated sites and features.

Energy Commission staff recommends that the PTNCL is eligible for listing on the NRHP under Criteria A and D and for the CRHR under Criteria 1 and 4. Under Criterion A/1, a resource is eligible if it is associated with “events that have made a significant contribution to the broad patterns of our history”. In the context of a Native American site where its importance is not recorded in written form, National Register Bulletin 38 (NPS 1998, pp. 12–13) makes it clear that the word “our” refers to the group that finds the property significant and “history” includes both traditional oral and written history. Important events can include specific events, or repetitive trends. Places referred to in Native American oral histories and creation stories, therefore, are potentially eligible.

Native American groups in the Mojave Desert consistently accord mythological importance to springs, petroglyph sites, and particularly trails systems. Trails across the desert mark the locations of travels of ancestral groups as they migrated to the confluence of the Gila and Colorado Rivers. Trails also facilitate dream travel to these places and the times when events mentioned in story and song occurred (Cleland 2005, p. 132). The particular trail that forms the backbone for this cultural landscape, the Halchidhoma Trail (CA-Riv-0053T), is well known from multiple historical and

¹⁶ The list of property types included in the PTNCL is not comprehensive; it should be added to as needed as new patterns are discovered.

ethnographic sources. It was an essential trade, transportation, and ritual route for Native American peoples and early European visitors in the Colorado Desert during prehistoric and historic times. This route was an essential connection between the Pacific Coast and the Southwestern deserts of Arizona and New Mexico.

Energy Commission staff, Western, and BLM consider the resources that make up the PTNCL to be significant under NRHP Criterion A (CRHR Criterion 1), for their ties to important events in American history. However, most property types associated with the PTNCL exist today as archaeological resources, such as petroglyphs, pot drops, cleared circles, and webs of intersecting trails. These sites are also considered Register-eligible under Criterion D/4 for their ability to yield information important in history and prehistory.

There are 29 trail segments with, and without, associated trailside features recorded along Parker-Blythe Transmission Line No. 2¹⁷. Fourteen have been recommended eligible for the NRHP and thus contributors (Cultural Resources Table 9). The other 15 segments have been recommended ineligible or indeterminate. These recommendations may need to be revisited as the Office of Historic Preservation has not reviewed or concurred with them.

METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

The purpose of this cultural resources analysis is to provide evidence of the ongoing public process by which the Energy Commission, Western, and BLM are jointly complying with local, state, and federal regulations to which each agency is variously subject. The Energy Commission, pursuant to section 25519, subsection (c) of the Warren-Alquist Act of 1974 (Act), is the lead agency for the purpose of complying with CEQA in relation to the certification of the proposed facility and the site on which the facility would operate, and is further responsible, pursuant to Section 25525 of the Act, for ensuring that the facility would conform with applicable State, local, or regional standards, ordinances, or laws.

THE PROJECT AREA OF ANALYSIS AND THE AREA OF POTENTIAL EFFECTS

A useful precursor to a cultural resources analysis under CEQA and NEPA and a requisite part of the Section 106 process (36 CFR Part 800) is to define the appropriate geographic limits for an analysis. The area that Energy Commission staff typically considers when identifying and assessing impacts to cultural resources under CEQA is referred to here as the “project area of analysis.” Energy Commission staff defines the Project Area of Analysis (PAA) as the area within and surrounding a project site and associated linear facility corridors. The area reflects the minimum standards set out in the Energy Commission Power Plant Site Certification Regulations (Cal. Code Regs., tit.

¹⁷ Trail segments identified along the Parker-Blythe Transmission Line No. 2 may be considered contributors to the PTNCL. These include: CA-SBR-1498, -1499, -1506, -1508, -1524, -8004, -8871, -8872, -8873, -8874, -8875, -8876/H, -8877, -8878, -8889, -8893, -8898, -8902, -8903, -8904, -8906, -8908, -8909, -8910, ; and CA-RIV-160, 872, -5984, -5985, 5987/H.

20, § 1701 et seq., appen. B, subd. (g)(2)) and is sufficiently large to facilitate considerations of archaeological, ethnographic, and built-environment resources. The project area of analysis is a composite, though not necessarily contiguous geographic area that accommodates the analysis of each of these resource types:

- For archaeological resources, the project area of analysis is minimally defined as the project ownership boundary, plus a buffer of 200 feet, the project tie line and access road routes, plus 100 feet to either side of the rights-of way for these routes and the project fiber optics on the existing transmission line, 25 feet either side of the transmission line, and access road rights-of-way..
- For ethnographic resources, the project area of analysis is expanded to take into account traditional use areas and traditional cultural properties which may be far-ranging, including views that contribute to the significance of the property. These resources are often identified in consultation with Native Americans and other ethnic groups, and issues that are raised by these groups may define the area of analysis.
- For built-environment resources, the project area of analysis is confined to one parcel deep from the project site footprint in urban areas, but in rural areas is expanded to include a half-mile buffer from the project site and above-ground linear facilities to encompass resources whose setting could be adversely affected by industrial development.
- For a historic district or a cultural landscape, staff defines the project area of analysis based on the particulars of each siting case.

Western and BLM conclude here that the PAA concept provides an appropriate areal scope for the consideration of cultural resources under NEPA and is consistent with the definition of the Area of Potential Effects (APE) in the Section 106 process (36 CFR § 800.16(d)). The PAA will, therefore, be equivalent to the APE for the purpose of the present analysis.

Inventory of Cultural Resources in the Project Area of Analysis

A cultural resources inventory, specific to each proposed or alternative action under consideration, is a necessary step in the staff effort to determine whether such actions may cause a substantial adverse change in the significance of any cultural resources (under CEQA) that are on or would qualify for the California Register of Historical Resources (CRHR); may significantly affect important historic and cultural aspects of our national heritage (under NEPA); or may, adversely affect any cultural resources that are on or would qualify for the NRHP, as required under Section 106.

The development of a cultural resources inventory entails working through a sequence of investigatory phases to establish the universe of cultural resources that will be the focus of the analysis of each proposed or alternative action. Generally the research process proceeds from the known to the unknown. These phases typically involve background research to identify known cultural resources, fieldwork to collect requisite primary data on not-yet-identified cultural resources in the vicinity of an action, and assessment of the results of any geotechnical studies or environmental assessments completed for a project site. The results of this research then support the development of determinations of historical significance for the cultural resources that are found.

Determining the Historical Significance of Cultural Resources

A key part of a cultural resources analysis under CEQA, NEPA, or Section 106 is to determine which of the cultural resources that a proposed or alternative action may affect are important or historically significant. (Each of these three regulatory programs uses slightly different terminology to refer to historically significant cultural resources. Clarifications on the use of the terms “historical resource,” “important historic and cultural aspects of our national heritage,” and “historic property” may be found in the “Cultural Resources Glossary” subsection at the end of this section.) Subsequent effects assessments are only made for those cultural resources that are determined to be historically significant. The criteria for evaluation and the requisite thresholds of resource integrity that, taken together, are the measures of historical significance vary among the three regulatory programs.

Evaluation of Historical Significance Under CEQA

CEQA requires the Energy Commission, as a lead agency, to evaluate the historical significance of cultural resources by determining whether they meet several sets of specified criteria. Under CEQA, the definition of a historically significant cultural resource is that it is eligible for listing in the CRHR, and such a cultural resource is referred to as a “historical resource,” which is a “resource listed in, or determined to be eligible by the State Historical Resources Commission, for listing in the CRHR”, or “a resource listed in a local register of historical resources or identified as significant in a historical resource survey meeting the requirements of section 5024.1(g) of the Public Resources Code,” or “any object, building, structure, site, area, place, record, or manuscript which a lead agency determines to be historically significant or significant in the architectural, engineering, scientific, economic, agricultural, educational, social, political, military, or cultural annals of California, provided the agency’s determination is supported by substantial evidence in light of the whole record” (Cal. Code Regs., tit. 14, § 15064.5(a)). The term, “historical resource,” therefore, indicates a cultural resource that is historically significant and eligible for listing in the CRHR.

Consequently, under the CEQA Guidelines, to be historically significant, a cultural resource must meet the criteria for listing in the CRHR. These criteria are essentially the same as the eligibility criteria for the NRHP. In addition to being at least 50 years old, a resource must meet at least one (and may meet more than one) of the following four criteria (Pub. Resources Code, § 5024.1):

- Criterion 1, is associated with events that have made a significant contribution to the broad patterns of our history;
- Criterion 2, is associated with the lives of persons significant in our past;
- Criterion 3, embodies the distinctive characteristics of a type, period, or method of construction, or represents the work of a master, or possesses high artistic values; or
- Criterion 4, has yielded, or may be likely to yield, information important to history or prehistory.

In addition, historical resources must also possess integrity of location, design, setting, materials, workmanship, feeling, and association (Cal. Code Regs., tit. 14, § 4852(c)).

Additionally, cultural resources listed in or formally determined eligible for the National Register of Historical Places (NRHP) and California Registered Historical Landmarks numbered No. 770 and up are automatically listed in the CRHR and are therefore also historical resources (Pub. Resources Code, § 5024.1(d)). Even if a cultural resource is not listed or determined to be eligible for listing in the CRHR, CEQA allows a lead agency to make a determination as to whether it is a historical resource (Pub. Resources Code, § 21084.1).

Assessing Action Effects

The core of a cultural resources analysis under CEQA, NEPA, or Section 106 is to assess the character of the effects that a proposed or alternative action may have on historically significant cultural resources. The analysis takes into account three primary types of potential effects which each of the three above regulatory programs defines and handles in slightly different ways. The three types of potential effects include direct, indirect, and cumulative effects. Once the character of each potential effect of a proposed or alternative action has been assessed, a further assessment is made as to whether each such effect is significant, relative to specific regulatory criteria under CEQA, NEPA, and Section 106.

Direct and Indirect Effects

Direct and indirect effects are those that are more clearly and immediately attributable to the implementation of proposed or alternative actions. Direct and indirect effects are conceptually similar under CEQA and NEPA. The uses of the concepts vary under Section 106 relative to their uses under CEQA and NEPA.

Direct and Indirect Impacts Under CEQA

In the abstract, direct impacts to cultural resources are those associated with project development, construction, and co-existence. Construction usually entails surface and subsurface disturbance of the ground, and direct impacts to archaeological resources may result from the immediate disturbance of the deposits, whether from vegetation removal, vehicle travel over the surface, earth-moving activities, excavation, or demolition of overlying structures. Construction can have direct impacts on historic built-environment resources when those structures must be removed to make way for new structures or when the vibrations of construction impair the stability of historic structures nearby. New structures can have direct impacts on historic structures when the new structures are stylistically incompatible with their neighbors and the setting, and when the new structures produce something harmful to the materials or structural integrity of the historic structures, such as emissions or vibrations.

Generally speaking, indirect impacts to archaeological resources are those which may result from increased erosion due to site clearance and preparation, or from inadvertent damage or outright vandalism to exposed resource components due to improved accessibility. Similarly, historic structures can suffer indirect impacts when project construction creates improved accessibility and vandalism or greater weather exposure becomes possible.

Ground disturbance accompanying construction at a proposed plant site, along proposed linear facilities, and at a proposed laydown area has the potential to directly

impact archaeological resources, unidentified at this time. The potential direct, physical impacts of the proposed construction on unknown archaeological resources are commensurate with the extent of ground disturbance entailed in the particular mode of construction. This varies with each component of the proposed project. Placing the proposed plant into this particular setting could have a direct impact on the integrity of association, setting, and feeling of nearby standing historic structures

Direct and Indirect Effects Under NEPA

The concepts of direct and indirect effects under NEPA are almost equivalent to those under CEQA. Direct effects under NEPA are those “which are caused by the [proposed or alternative] action and [which] occur at the same time and place” (40 CFR § 1508.8(a)). Indirect effects are those “which are caused by the [proposed or alternative] action and are later in time or farther removed in distance, but are still reasonably foreseeable” (40 CFR § 1508.8(b)).

Direct and Indirect Effects Under Section 106

The Section 106 regulation narrows the range of direct effects and broadens the range of indirect effects relative to the definitions of the same terms under CEQA and NEPA. The regulatory definition of “effect,” pursuant to 36 CFR § 800.16(i), is that the term “means alteration to the characteristics of a historic property qualifying it for inclusion in or eligibility for the National Register.” In practice, a “direct effect” under Section 106 is limited to the direct physical disturbance of a historic property. Effects that are immediate but not physical in character, such as visual intrusion, and reasonably foreseeable effects that may occur at some point subsequent to the implementation of the proposed undertaking are referred to in the Section 106 process as “indirect effects.”

Cumulative Impacts

Cumulative Impacts are slightly different concepts under CEQA and NEPA, and are, under Section 106, undifferentiated as an aspect of the potential effects of an undertaking, of a proposed or alternative action. The consideration of cumulative impacts reaches beyond the project area of analysis or the area of potential effects. It is a consideration of how the effects of a proposed or alternative action in those areas contributes or does not contribute to the degradation of a resource group or groups that is or are common to the project area of analysis and the surrounding area or vicinity.

Cumulative Impacts Under CEQA

A cumulative impact under CEQA refers to a proposed project's incremental effects considered over time and taken together with those of other nearby past, present, and reasonably foreseeable future projects whose impacts may compound or increase the incremental effect of the proposed project” (Pub. Resources Code sec. 21083; Cal. Code Regs., tit. 14, secs. 15064(h), 15065(a)(3), 15130, and 15355). Cumulative impacts to cultural resources in a project vicinity could occur if any other existing or proposed projects, in conjunction with the proposed project, had or would have impacts on cultural resources that, considered together, would be significant. The previous ground disturbance from prior projects and the ground disturbance related to the future construction of a proposed project and other proposed projects in the vicinity could have

a cumulatively considerable effect on archaeological deposits, both prehistoric and historic. The alteration of the natural or cultural setting which could be caused by the construction and operation of a proposed project and other proposed projects in the vicinity could be cumulatively considerable, but may or may not be a significant impact to cultural resources.

Cumulative Impacts Under NEPA

As noted in 40 CFR § 1508.7, “a [C]umulative impact is the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor, but collectively significant actions, taking place over a period of time.” Cumulatively significant impacts are part of the consideration when determining the intensity of a significant effect [40 CFR § 1508.27(b)(7)].

Cumulative Effects Under Section 106

The Section 106 regulation makes explicit reference to cumulative effects only in the context of a discussion of the criteria of adverse effect (36 CFR § 800.5(a)(1)). Cumulative effects are largely undifferentiated as an aspect of the potential effects of an undertaking. Such effects are enumerated and resolved in conjunction with the consideration of direct and indirect effects.

Assessing the Significance of Action Effects

Once the character of the effects that proposed or alternative actions may have on historically significant cultural resources has been determined, the severity of those effects needs to be assessed. CEQA, NEPA, and Section 106 each have different definitions and tests that factor into decisions about how severe, how significant the effects of particular actions may be.

Significant Impacts Under CEQA

Under CEQA, “a project that may cause a substantial adverse change in the significance of an historical resource is a project that may have a significant effect on the environment” (Pub. Resources Code, § 21084.1). Thus, staff analyzes whether a proposed project would cause a substantial adverse change in the significance, that is, the CRHR eligibility, of all historical resources identified in the Cultural Resources Inventory. The degree of significance of an impact depends on:

- The cultural resource impacted;
- The nature of the resource’s historical significance;
- How the resource’s historical significance is manifested physically and perceptually;
- Appraisals of those aspects of the resource’s integrity that figure importantly in the manifestation of the resource’s historical significance; and how much the impact will change those integrity appraisals.

Significant Effects Under NEPA

Significant effects under NEPA require considerations of both context and intensity (40

CFR § 1508.27). In the case of a site-specific action, significance would usually depend upon the effects in the locale rather than in the world as a whole. Both short- and long-term effects are relevant (40 CFR § 1508.27(a)). A consideration of intensity involves the consideration of the severity of an impact.

Adverse Effects Under Section 106

As noted in 36 CFR § 800.5(a)(1), “[A]n adverse effect is found when an undertaking may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the National Register in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. Consideration shall be given to all qualifying characteristics of a historic property, including those that may have been identified subsequent to the original evaluation of the property's eligibility for the National Register. Adverse effects may include reasonably foreseeable effects caused by the undertaking that may occur later in time, be farther removed in distance or be cumulative.” A formal effect finding under Section 106 relates to the proposed or alternative action as a whole, rather than to the individual resources.

Resolving Significant Effects

The concluding phase in a cultural resources analysis, whether under CEQA, NEPA, or Section 106, is to (avoid) or mitigate those effects of a proposed or alternative action that have been found to be significant. The terminology used to describe the process of effects resolution differs among the three regulatory programs. The resolution of significant effects under CEQA involves the development of mitigation measures that would avoid the adverse impact or reduce the potential impact to a less than significant level or to the extent feasible (14 CCR § 15126.4). Mitigation under NEPA includes proposals that avoid or minimize any potential significant adverse effects of a proposed or alternative action on the quality of the human environment (40 CFR § 1502.4). The definition of mitigation in the NEPA regulation includes the development of measures that would avoid, minimize, or rectify significant adverse effects, progressively reduce or eliminate such effects over time, or provide compensation for such effects (40 CFR § 1508.20). The Section 106 process directs the resolution of adverse effects through the development of proposals to avoid, minimize, or mitigate such effects (36 CFR § 800.6(a)).

The present analysis seeks to resolve the potentially significant adverse effects of the proposed and alternative actions on cultural resources through the development of measures that satisfy the common conceptual threads of effects resolution in CEQA, NEPA, and Section 106. Energy Commission staff proposes Condition of Certification **CUL-10** as the basis for coordinating CEQA compliance requirements with those required of Western and BLM under NEPA and Section 106. The Western/BLM proposes to use the present cultural resources analysis and its consultation efforts under Section 106, which includes the negotiation and drafting of a Memorandum of Agreement (MOA), to evidence its compliance with NEPA. Energy Commission staff also proposes additional conditions of certification (**CUL-1** through **CUL-9** and **CUL 11-12**) that the applicant would implement in the event that the staffs of the Energy Commission and the Western/BLM should become unable to resolve differences of professional opinion on the disposition of a cultural resource during the construction,

operation, maintenance, or decommissioning and closure of the proposed, or alternative actions. The applicant's implementation of the terms of the MOA and of the additional conditions of certification would ensure compliance with applicable LORS, in addition to compliance with CEQA, NEPA, and Section 106.

Assessment of Impacts and Mitigation Discussion

Construction Effects

The main facility footprint will adversely and substantially impact nearly all of the features and artifact concentrations recently recorded within the Rice AAF and western periphery of Camp Rice. Because these resources are assumed to be contributing properties to the World War II DTC/C-AMA, the proposed project will also directly impact the DTC Cultural Landscape (DTCCL). In addition, possible construction impacts may also occur to 23 previously recorded sites recommended eligible for the NRHP along the Parker-Blythe Transmission Line No. 2. These include: RIV-5983H, -5985T, -5987/H, -5988H, -5990H; SBR-1511, -1506, -1508, -2525, -8871/H, -8877, -8878, -8882, -8908, -8892, -8897, -8902, -8903, -8904, -8906, -8907, -8909, and -8910. Cultural Resources Table 10 lists assumed eligible resources subject to direct project impacts.

CULTURAL RESOURCES Table 10
NRHP and CRHR-Assumed Eligible Cultural Resources Subject to Direct Project Impacts

Resource	Resource Descriptions	NRHP/CRHR Eligibility
DTC/C-AMA Cultural Landscape	Rice AAF/Camp Rice (with associated features and artifact concentrations), as well as Riv-5987, -5988, and -5990	Assumed Eligible
Prehistoric Trails Network Cultural Landscape	Prehistoric Trails and contributing sites noted along the Parker-Blythe 161 kV Transmission Line No. 2 (Riv-5985, -5987(Locus A); SBR-1506, -1508, -8871, -8877, -8878, -8901, -8903, -8904, -8906, -8908, -8909, -8910)	Assumed Eligible
Lithic Scatters/ Quarries	SBR-1511, -8882, -8892-, -8897, -8907	Assumed Eligible*
Geoglyph	SBR-2525	Assumed Eligible*
Mining Camp	RIV-5983H	Assumed Eligible*
Historic Road	Road-1	Assumed Eligible

* Assumed Eligible resources with asterisks are ones that were recommended eligible by Schaeffer et al. (1998) but that have not received concurrence from the Office of Historic Preservation.

Operation Effects

With respect to direct impacts, if, during operation of the RSEP, the project owner should plan any changes or additions entailing significant amounts of ground disturbance, the project owner would have to petition the Energy Commission to review the environmental impacts of those activities and approve the plan. Cultural resources staff would then determine if previously undisturbed sediments would be affected by the planned activities and, if so, recommend the application of existing conditions or devise new ones to mitigate any impacts to significant known or newly identified cultural resources. Consequently, at this time staff has recommended no conditions of certification addressing operation direct impacts.

Project Closure and Decommissioning Effects

Cultural resources within the proposed RSEP main facility footprint are expected to be destroyed during facility construction. Therefore the closure and decommissioning of the proposed project is unlikely to cause additional impacts to known or previously unknown cultural resources. However, sites within the linear facilities corridor and near the boundary of the proposed project footprint may still exist after RSEP construction and associated archaeological data recovery. These sites could be impacted by activities associated with project closure and decommissioning.

As for any changes or additions to the RSEP during operation, as discussed above, the project owner, prior to any decommissioning activities, would petition the Energy Commission to review and approve a decommissioning plan, and cultural resources staff would then determine if previously undisturbed sites or sediments would be affected by the decommissioning. If so, staff could then recommend conditions to mitigate any decommissioning impacts to significant known or newly identified cultural resources. Consequently, at this time staff has recommended no conditions of certification addressing decommissioning impacts.

CUMULATIVE IMPACTS AND MITIGATION

The RSEP is proposed to be sited on private lands and is subject to CEQA review. A portion of the proposed generation tie line would traverse land managed by the BLM. The project would interconnect with a Western transmission line. Under CEQA Guidelines, “a cumulative impact consists of an impact which is created as a result of the combination of the project evaluated in the EIR together with other projects causing related impacts” (14 Cal Code Regs §15130(a)(1)). Cumulative impacts must be addressed if the incremental effect of a project, combined with the effects of other projects is “cumulatively considerable” (14 Cal Code Regs §15130(a)). Such incremental effects are to be “viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects” (14 Cal Code Regs §15164(b)(1)). Together, these projects comprise the cumulative scenario which forms the basis of the cumulative impact analysis.

CEQA also states that both the severity of impacts and the likelihood of their occurrence are to be reflected in the discussion, “but the discussion need not provide as great detail as is provided for the effects attributable to the project alone. The discussion of cumulative impacts shall be guided by standards of practicality and reasonableness,

and shall focus on the cumulative impact to which the identified other projects contribute rather than the attributes of other projects which do not contribute to the cumulative impact” (14 Cal Code Regs §15130(b)).

NEPA states that cumulative effects can result from individually minor but collectively significant actions taking place over a period of time” (40 CFR §1508.7). Under NEPA, both context and intensity are considered. When considering intensity of an effect, we consider “[w]hether the action is related to other actions with individually minor but cumulatively significant impacts. Significance cannot be avoided by terming an action temporary or by breaking it down into small component parts.” 40 CFR §1508.27(b)(7).

The intensity, or severity, of the cumulative effects should consider the magnitude, geographic extent, duration and frequency of the effects (CEQ, 1997). The magnitude of the effect reflects the relative size or amount of the effect; the geographic extent considers how widespread the effect may be; and the duration and frequency refer to whether the effect is a one-time event, intermittent, or chronic (CEQ, 1997).

Geographic Extent

The geographic scope for this project is fairly localized around the RSEP ownership boundary, however, given the nature of the Colorado Desert Valley system, the RSEP project area should not be limited to the Rice Valley, but should also include its northwest continuation into the Ward Valley (that includes Bristol and Cadiz Dry Lake system). As mentioned above, the valleys in this region are contiguous and drainages often flowed into one another. In terms of temporal limits, the immediate mountain ranges should also be included in this scope: Turtle Mountains, Whipple Mountains, Chemehuevi Mountains, Old Woman Mountains, and Arica Mountains. These mountains represent the mining activities that took place in the immediate area and should be considered a part of this scope in order to encompass a broader historic context for the region (i.e., pre-dates the construction, operation, and closure of Rice AAF and Camp Rice).

Existing Cumulative Conditions

Four existing projects occur within the immediate vicinity of the RSEP project site: (1) the Rice Valley Grazing Allotment (which roughly borders the western, southern, and eastern boundaries of the RSEP); (2) the Arizona-California Railroad (parallels the northern boundary of the RSEP Project Area); (3) the Colorado River Aqueduct (also parallels the northern RSEP site boundary); and (4) Westerns’ Parker Dam-Blythe transmission line #2. The railroad and aqueduct hold particular significance, as they contribute to the development of the area (transportation, mining, etc.).

Modification/maintenance of these features may impact the archaeological components of Camp Rice. Seven other existing projects are located within Rice Valley; however, they are well outside of the range of possible impacts to cultural resources for the RSEP proposed project area. As the RSEP will affect the Rice AAF and Camp Rice archaeological resources, the project will significantly alter the cultural environment of the area.

Future Foreseeable Projects

Foreseeable Projects in the Project Area

A solar thermal power plant is proposed for the Ward Valley (Table 3, ID# B), approximately 5 miles northwest of the RSEP Project area. Impacts caused by the construction of this project will not impact the RSEP site, although it may affect the overall context of the area (that is mining districts in the immediate area).

Foreseeable Renewable Project in the California Desert

A solar thermal power plant (Table 3, ID# F) roughly 26 miles west of the RSEP at Cadiz Lake may affect drainage systems from Bristol/Cadiz Lakes into the Danby Dry Lake and subsequently Rice Valley.

Overall Conclusion – Cumulative Impacts

The RSEP impacts, when combined with impacts from past, present, and reasonably foreseeable projects, contribute in a small but significant way to the cumulatively considerable adverse impacts for cultural resources at both the local and regional levels. The majority of the proposed future projects examined in this analysis would likely undergo CEQA and/or NEPA review. Sites that could not be avoided would be tested to evaluate significance. Register-eligible sites would be subject to historical documentation or data recovery excavations to mitigate impacts. To mitigate to the extent reasonable the region-wide, substantial cumulative impact to the DTCCCL identified in this analysis, staff recommends Condition of Certification **CUL-1**

DTCCCL Landscape Documentation and Possible Nomination Program

RSEP shares the historical military training sites associated with the DTC/C-AMA with three other projects currently under consideration in the southern desert: Blythe Solar Power Project, Genesis Solar Energy Project, and Palen Solar Power Project. The DTCCCL Program would provide the data for consideration of the DTCCCL eligibility for NRHP nomination.

It is staff's intention to allow future projects, under Energy Commission jurisdiction, that would contribute to the cumulative impacts to cultural resources in the region to contribute to this mitigation program, along with any contemporaneous and future projects not under Energy Commission jurisdiction that would contribute to the cumulative impacts to cultural resources in the region. It is staff's intention to allow future projects that would contribute to the cumulative impacts to cultural resources in the region to contribute to this mitigation program, whether under Energy Commission jurisdiction or not.

The cost of this program would be divided among the project owners in direct proportion to the number of acres each project would enclose or otherwise disturb. Staff feels that the number of acres disturbed is the most equitable measure of impacts to cultural resources for all related projects. Each project area has a different relative density of archaeological sites, but the number of buried archaeological sites for each is unknown. So the site counts may change dramatically and unexpectedly during future archaeological exploration and construction.

Considering these unknown and unquantifiable factors, staff considers the number of acres disturbed by each project to be a reasonable and concrete proxy. Condition of Certification **CUL-1** require the RSEP owner to contribute \$25 per acre disturbed to a special Energy Commission fund to finance the documentation and possible NRHP nomination of the DTCCL. Staff arrived at this amount by estimating what the cost of each program would be, including overhead costs (\$300,000), dividing that by the total number of acres the projects together would disturb or enclose (11,903 acres), and rounding to the nearest \$5.00 increment, for a levy of \$25 per acre. It is likely that RSEP would start construction after the DTCCL study is already in progress. Therefore, it is reasonable to partially exempt RSEP from contributing to the first phase of the study, which would produce the historic context, evaluation criteria, and research questions that will guide data recovery from DTCCL archaeological sites. It would not, however, be reasonable to exempt RSEP from the entire cost of the first phase, as the PI-Historian would have to revise the context to include those aspects of the DTCCL that are specific to the RSEP. This is expected to take approximately one-quarter (25%) of the total phase one hours for the RSEP site, compared to the hours necessary on the other three projects. The hours allocated to the first phase of the study represent 16 percent (16%) of the total hours in the DTCCL budget. Therefore, RSEP would be credited with a 12% discount, for a levy of \$22 per acre disturbed.

Staff is recommending an identical condition for the project owners of the Palen Solar Power Project, Genesis Solar Energy Project, and Blythe Solar Power Project. Any additional coordination among project owners that can be negotiated, beyond that specified here, is welcomed and encouraged. Applicants may make their contributions to the DTCCL fund prior to certification. Pre-certification contributions to the two funds would not affect a project's certification prospects in any way. The applicants making such contributions would do so, at their own risk, as a means of advantaging their schedule. Western and BLM concur with this strategy.

DTCCL Program Elements

The DTCCL program will have a historian for a principal investigator, who will collaborate with a historical archaeologist in the tasks of documenting and nominating the DTCCL to the NRHP. The DTCCL Historical Archaeologist will also train the individual project historical archaeologists and their crews in the accurate and consistent field identification and recording of historic-period artifacts, with an emphasis on those associated with the DTC/C-AMA. The funding for this program, would utilize the mechanism and contribution basis indicated in **CUL-1**.

Energy Commission staff will engage a historian to serve as the principal investigator (PI) and historian for the following research on the DTCCL. The DTCCL PI-Historian must have the following qualifications:

1. At a minimum, an Master of Arts (M.A.) in history, with a specialization in World War II military history.
2. Education and training that meet the U.S. Secretary of the Interior's Professional Qualifications Standards for Historian, as published in Title 36, Code of Federal Regulations, part 61;

3. Demonstrated ability to conduct and report on historical research; and
4. At least three years of full-time professional experience managing research projects.

The Energy Commission will engage a DTCCL Historical Archaeologist to collaborate with the PI-Historian. The PI-Historian will manage and coordinate the research activities required in this condition, report on progress to staff, and complete Task A. Staff will have final decisionmaking authority regarding budget and technical cultural resources matters.

The Energy Commission will provide copies of the AFC, data responses, confidential cultural resource documents, Revised Staff Assessment (RSA), Supplemental Staff Assessment, and other relevant documents for this project to the DTCCL PI-Historian and Historical Archaeologist.

A. Historical Study:

The DTCCL PI-Historian will:

1. Develop an annotated bibliography, including oral history sources, to establish the context, themes, contributing resource types, material culture, period of significance, and boundaries for the DTCCL;
2. Create a time line of DTC/C-AMA activities across the entire maneuver area, including Arizona;
3. Write the context, emphasizing material culture, and define the themes, contributor resource types, and period of significance;
4. Produce a general map of the historical DTC/C-AMA;
5. Compile a detailed map charting the maneuvers conducted on each of the four project sites (RSEP, Palen Solar Power Project, Blythe Solar Power Plant, and Genesis Solar Energy Plant);
6. Compile a list of known DTCCL contributors, with a description and individual map plot of each; and
7. Assist Energy Commission staff in drafting a map showing all DTCCL elements and drawing a provisional boundary for the DTCCL from the historical perspective; and provide written justification for the boundary.

The DTCCL PI-Historian will provide the products of 2 through 6 to the three project CRSs.

The DTCCL PI-Historian will submit the draft DTCCL historical documentation to staff and to the BLM Palm Springs Field Office archaeologist for review and approval.

B. Historical Archaeological Study

The Energy Commission will obtain the services of a historical archaeologist to serve as DTCCCL Historical Archaeologist. The DTCCCL Historical Archaeologist's training and background must meet the U.S. Secretary of Interior's Professional Qualifications Standards for Historical Archaeology, as published in Title 36, Code of Federal Regulations, part 61. The resume of the DTCCCL historical archaeologist must demonstrate familiarity with the artifacts, environmental modifications (deliberate and incidental, including tank tracks), and trash disposal patterns associated with World War II land-based army activities, and knowledge of the full range of late nineteenth and early-to-mid-twentieth-century domestic can, bottle, and ceramic diagnostic traits. The resume of the proposed DTCCCL Historical Archaeologist will be submitted to staff for review and approval.

The DTCCCL Historical Archaeologist will:

1. Synthesize the present state of knowledge of DTCCCL historical archaeology in the Rice Valley, Chuckwalla Valley, and Palo Verde Mesa and identify significant gaps in this knowledge, based on all pertinent literature, including published monographs and papers, unpublished reports in the files of the CHRIS and the BLM's Palm Springs Field Office, and on consultation with archaeologists actively conducting research in this region, particularly those based in academia;
2. Develop a comprehensive historic-period archaeological context for the DTCCCL;
3. Have low-altitude aerial photography of the Rice Valley, Chuckwalla Valley, and Palo Verde Mesa flown, and analyze the results for evidence of larger-scale DTCCCL (or other historic-period) activities and any unrecognized site types. If any such sites are identified within the project areas of the RSEP, Palen Solar Power Project, Blythe Solar Power Project, or Genesis Solar Energy Project, notify the appropriate CRS(s) and have these resources recorded and added to the project's cultural resources inventory;
4. From the historical archaeological context, literature synthesis, and aerial photography, identify and describe the full range of archaeological resources known for the DTCCCL and posit any additional resources that, while not known, are strongly suggested by the context and synthesis;
5. From the historical archaeological context and the literature synthesis, formulate specific research questions:
 - a. To fill significant gaps in our knowledge of the DTCCCL history of this area
 - i. Specify what kinds of resources have the relevant data
 - b. Answerable with data from known archaeological resources
 - i. Specify the methods for making this determination
 - c. To determine the presence or absence of additional archaeological resources not presently known but likely

- d. To definitively distinguish Desert Strike sites from DTC/C-AMA sites
 - i. Army records for locations of Desert Strike activities may facilitate eliminating some ambiguous sites not in those locations as Desert Strike sites;
6. Develop criteria for definitively attributing archaeological sites to the DTCCL based on archaeological traits;
7. Compile location data on known DTCCL archaeological elements, direct the drafting of detailed GIS-based maps of the various site types and their spatial distributions, and draw on a map a provisional boundary for the DTCCL from the archaeological perspective, with a written justification for the boundary. The Energy Commission will contract with an outside firm to perform the drafting;
8. Train the Project Historical Archaeologists for the RSEP, Palen Solar Power Project, Genesis Solar Energy Project, and Blythe Solar Power Project to correctly and consistently identify and record the historic-period military and domestic artifacts likely to be encountered on the these project sites and assist them in the development of field recording forms for these artifacts and sites; and
9. Assist the Project Historical Archaeologists for the RSEP, Palen Solar Power Project, Genesis Solar Energy Project, and Blythe Solar Power Project to train their field crews to correctly and consistently identify and record the historic-period military and domestic artifacts likely to be encountered on the these project sites and to correctly and completely fill out the field forms developed for historic-period sites.

The Energy Commission will provide the products of 1–8 to the four project CRSs.

The DTCCL PI-Historian will submit the draft DTCCL historic-period archaeological documentation to staff and the BLM Palm Springs Field Office archaeologist for review and approval.

C. Possible NRHP nomination of the DTCCL:

After all data recovery for the four projects is completed and reported, the DTCCL PI-Historian will confer with the DTCCL Historical Archaeologist to decide if the DTCCL is probably eligible for the NRHP and, if so, will collaborate on a NRHP multiple property nomination for the DTCCL under Criteria A, C, and D. If the DTCCL PI-Historian and the DTCCL Historical Archaeologist agree that a DTCCL nomination is appropriate, the DTCCL nomination will include:

1. Definition of the resource;
2. DTCCL probable contributing resource types, known and as-yet-unknown:
 - a. tank tracks,
 - b. refuse (primarily food can) scatter,
 - c. refuse (other activities, e.g., auto-related; ± food) scatter,
 - d. multiple-episode refuse dump,

- e. foxhole/temporary defensive position,
 - f. temporary camp-related (cleared areas for tents),
 - g. semi-permanent camp-related (paths, activity areas, varied shelter sizes and shapes),
 - h. features (hearths, other), and
 - i. other;
3. Historical background and context;
 4. Justification of eligibility;
 5. Period of significance and justification for POS;
 6. Identification of contributors; assistance to Energy Commission staff in the creation of a map of contributors, archaeologically confirmed sites, and site descriptions of all; and
 7. Provision for adding additional contributing resources to the district as further survey is done.

The BLM will submit the approved DTCCCL NRHP nomination to the State Historical Resources Commission, to initiate the process of formal consideration by the Keeper of the National Register and track and facilitate the review of the nomination to acceptance, including required revisions and additions, or final rejection.

If the DTCCCL PI-Historian and the DTCCCL Historical Archaeologist agree that a DTCCCL nomination is not appropriate, the DTCCCL PI-Historian will write and submit a report that will include a summary of the evidence justifying the ineligibility determination, documenting all research activities conducted on the basis of the applicant's funding, and synthesizing all data from the DTCCCL investigation to create a document that BLM can use to manage the DTCCCL resources..

D. Management Plan and Information Dissemination:

The Energy Commission will assist the BLM Palm Springs Field Office archaeologist in seeking BLM recognition for the DTCCCL as a resource requiring special management status, if NRHP eligibility is not supported:

1. For managing known, unimpacted resources
2. For adding further contributing resources to the district as further survey is done

The DTCCCL PI-Historian will collaborate with the DTCCCL Historical Archaeologist to prepare a research paper, interpreting the implications of the DTCCCL data for our understanding of WWII combat training history, and submit it to a peer-reviewed journal.

The DTCCCL PI-Historian will create or direct the creation of an provide an instruction module for use in local school districts, based on the data compiled by the DTCCCL PI-Historian and the DTCCCL Historical Archaeologist. The Energy Commission will obtain the services of an exhibit preparer and the PI-Historian will direct the preparer to craft materials and/or a display for existing public interpretation venues at local museums (such as the nearby George S. Patton Memorial Museum or Wiley's Well rest area) that interpret the DTCCCL for the public, based on the data compiled by the DTCCCL PI-Historian and the DTCCCL Historical Archaeologist. The Energy Commission and the BLM will offer the materials for use and display.

The DTCCCL PI-Historian will also explore other modes of public dissemination of DTCCCL data and propose these, with budgets, to staff. The PI-Historian and Historical Archaeologist will act as technical advisers for these products, but the Energy Commission will contract with another firm to create them. Some possibilities are noted here, but the PI-Historian's proposals should not be limited to these:

- A DTCCCL website and chatroom for WWII veterans and history buffs to acquire and exchange information;
- A hiking or off-road-vehicle trail connecting DTCCCL archaeological remains of particular interest (and locations where artifacts of archaeological interest are no longer present), such as the more permanent camps and air bases. This trail and a map providing GPS coordinates, descriptions, historical information, and historic-period photographs could be developed with BLM and made available to visitors; a model for such a trail is the California Backcountry Discovery Trails system;
- An over-flight video, with a narration identifying and providing the history of the DTCCCL contributors that are better observed from the air, such as the airbases, interspersed with historic-period film footage of related DTCCCL activities.

DTCC/C-AMA Cultural Landscape, Project-Specific Mitigation for RSEP Impacts to Contributors

The DTCCCL and its potential contributors will be defined and impacts to these resources will be evaluated by two specialists: a DTCCCL PI and Historian and a DTCCCL Historical Archaeologist. The responsibilities of each specialist are outlined below and in condition of certification **CUL-2**.

The DTCCCL PI-Historian will be a specialist in World War military history who will write a context for the DTCCCL expanding upon, but not duplicating the efforts of Bischoff (2000 and 2009). The context will emphasize material culture, create a timeline of activities across the entire maneuver area and result in detailed maps that focus on the four project areas and the maneuvers that took place in each. This specialist will also conduct oral history interview with veterans and synthesize previously recorded interviews.

The DTCCCL Historical Archaeologist will be a specialist in the identification, analysis and interpretation of the artifacts, environmental modifications (e.g. tank tracks), and trash disposal patterns associated with the early phases of WWII land-based army activities. In addition, the specialist will be knowledgeable of the full range of late

nineteenth and early-to-mid-twentieth-century can, bottle, and ceramic diagnostic traits. As some of these skills are rare, the DTCCL Historical Archaeologist will be responsible for training the field crews with the above skills so they can accurately complete in-field artifact analyses. The specialist will also be responsible for accurately and consistently determining if each RSEP site is associated with the DTCCL, or some other historic time period such as pre-1940s mining and ranching. This specialist will also ensure that the field work on the historic archaeological sites at all four solar project sites is consistent, and of high quality. This person will also facilitate data sharing between different projects, project owners, and companies, if necessary.

Together, the DTCCL PI-Historian and the DTCCL Historical Archaeologist will write a context that: refines the research questions that will be addressed, identifies the specific data sets needed to answer these questions, develops mitigation measures for the relevant site types, and establishes the analytical standards that will be met. Until these refinements take place, research and mitigation will be modeled on Bischoff's (2000 and 2009) context, under the guidance of BLM and Energy Commission archaeologists.

Finally, if both DTCCL specialists agree that the DTCCL is eligible for listing on the NRHP, they will jointly write a nomination form under Criterion D and any other Criterion they think is appropriate. The nomination will list the resources that they have identified from all four projects as contributors. Resources will be identified as contributors or non-contributors on the basis of the contexts developed by the specialists and on the basis of the data recovered from each potential contributor during the evaluation and data recovery activities that staff has recommended for each known resource that would be impacted by the RSEP and the other two projects. The evaluation of each resource as a potential DTCCL contributor would suffice as well to evaluate it as an individual resource if the DTCCL specialists should agree that the DTCCL is not eligible for listing on the NRHP.

PROJECT ALTERNATIVES

	Proposed Alternative	Acres	MW	Federal Nexus
1	Proposed Project	1,410 acres + 10.0 mile long transmission line corridor	150	Yes
2	Reduced Acreage (same site location)	1,270 acres + 10.0 mile long transmission line corridor	~148	Yes
3	North of Desert Center (alternate location), includes realignment and reconductoring of existing SCE 161/230kV line.	1,410 acres + 4.6 mile long transmission line corridor	150	Yes
4	Rice Valley Road Transmission Line	1,410 acres + 13.9 mile long transmission line corridor	250	Yes
5	No Project/No Action	0	0	No

Reduced acreage Alternative

The Reduced Acreage Alternative would be 7.2 percent smaller than the proposed project. It would be located in the same 2,560-acre square-shaped parcel within the larger 3,324-acre ownership property as the proposed project. Although the overall heliostat field distance from the central tower would be reduced, the number of heliostats would remain the same. The heliostat field (plus the evaporation pond and administration areas) would occupy about 1,270 acres instead of the 1,370 acres required for the proposed project. The receiver location would remain the same, with the edges of the field contracting towards the center. The heliostat footprint of the Reduced Acreage Alternative is shown in **Alternatives Figure 2**. The site layout, 653-foot total height of the solar tower and receiver, and transmission interconnection to Western's Parker-Blythe #2 transmission line would be the same as the proposed project. The generation output would be reduced by approximately 2 MW.

Similar to the proposed project, the Reduced Acreage Alternative would transmit power to the grid through the planned Western substation to be located adjacent to Western's Parker-Blythe #2 161-kV transmission line.

The Reduced Acreage Alternative is evaluated in this SA/DEIS because it would eliminate about 100 acres of the proposed project footprint, reducing impacts to ephemeral washes, the loss of land considered habitat for the state and federally listed threatened desert tortoise and impacts to the historic Rice Airfield. The Reduced Acreage Alternative would allow the applicant to contribute clean, renewable energy to help meet the State's energy goals, while reducing impacts to the desert environment. A limited acreage alternative was suggested in scoping comments.

Setting and Existing Conditions

All of the aspects of the setting and existing conditions as set out above for the proposed project are also pertinent to this alternative except the project description. As configured, the reduced heliostat field would be located on land that was previously surveyed for cultural resources in connection with the proposed project. As the ownership property dimensions remains the same, the same number of previously recorded resources still fall with the project area. Until final plans are set, staff cannot determine what impacts will occur for the Rice AAF.

Cultural Resources Inventory

CH2MHILL's record search and field survey for the proposed Reduced Alternative configuration falls within the boundary of the proposed project ownership property. Thus, additional records search and field survey were not required. Future actions, as part of the Conditions of Certification, will be required to update site records and address any deficiencies in documentation.

Assessment of Impacts and Discussion of Mitigation

Staff concludes that impacts would be nearly identical to the proposed Project, with most of the features and artifact concentrations associated with Rice AAF will still be destroyed. Staff recommends that impacts of this alternative on cultural resources would have to be avoided or mitigated by means of data recovery, with specific modes of data recovery detailed in a Memorandum of Agreement (MOA), to be negotiated and

signed by the Western, BLM, the State Historic Preservation Officer, the Energy Commission, any Native American tribes or groups who opt to sign, and, possibly, the applicant. Western has initiated consultation with the State Historic Preservation Officer discussing the area of potential effects, eligible sites, effects and the MOA.

CEQA/NEPA Level of Significance of Impacts

Staff, Western, and BLM would assume that all construction impacts, direct, indirect, and cumulative, to all eligible and staff-assumed-eligible cultural resources located in the APE of this alternative would be substantial and adverse, and significant with respect to CEQA. Staff, Western, and BLM also assume that these impacts would be reduced to a less-than-significant level by the implementation of **CUL-1** through **CUL-12** and mitigation measures outlined in the MOA, and would be less-than-significant with respect to CEQA. Staff would also provide mitigation measures for the appropriate treatment of potentially eligible archaeological resources discovered during construction of this alternative, should it be built, and these measures would reduce the alternative's impact on discovered Register-eligible archaeological resources to less than significant.

NORTH OF DESERT CENTER ALTERNATIVE

The North of Desert Center Alternative would be a 150 MW solar thermal facility located on approximately 2,643 acres of land. It is located along Desert Center Rice Road (State Route 177) east of Kaiser Road, north of Oasis Road, and approximately 1.6 miles north of I-10. The North of Desert Center Alternative is primarily private land with smaller sections of BLM land in the eastern portion of the site. It is largely fallow agricultural land. The existing SCE 161-kV transmission line (from the Blythe-2 substation to the Eagle Mountain-1 substation) that traverses the alternative site would be realigned to roughly follow the site boundary. A new 0.125-mile transmission line (along Osborne Ave.) and substation would interconnect to the realigned SCE line at the northeast boundary of the site. The boundaries and transmission realignment of the North of Desert Center Alternative are illustrated in **Alternatives Figure 2**.

Setting and Existing Conditions

The North of Desert Center Alternative is composed largely of private properties (agricultural land) but also includes undeveloped BLM land, and some County of Riverside land. The alternative site is located along Desert Center Rice Road (State Route 177) east of Kaiser Road, north of Oasis Road, and approximately 1.6 miles north of I-10 in Riverside County, California. The alternative site is roughly 38 miles southwest of the RSEP with a varying environmental setting, in that nearly 70% of the land proposed for the North of Desert Center Alternative is disturbed by past and current agricultural operations. The remaining landscape is similar to the Palen Solar Project and consists of desert washes, sandy dunes, and lower alluvial fan sediments. Major water sources are limited to the Colorado River, which lies approximately 50 miles east of the alternative site. However, when rainwater exceeds evaporation and occasional flooding occurs, Palen Lake (approximately 12 miles east of the alternative) will fill, creating a temporary water source. The Colorado Desert has a long and culturally rich past beginning thousands of years ago and continuing through the World War II desert training activities.

A Cultural Resources Class III Report for the Proposed Palen Solar Power Project, Riverside County, California (Tennyson and Apple, 2009) and *Palen Solar Power Project Application for Certification, Volume I* (AECOM, 2009) provide a brief cultural context for the North of Desert Center Alternative. Staff of Applied Earth Works, Inc. conducted a records search for the North of Desert Center Alternative at the Eastern Information Center of the California Historical Resources Information System on February 16, 2010. The records search indicated that a total of nine surveys had been conducted within a one-mile radius of the alternative site. Of these, four surveys included minor portions of the proposed alternative site. The records search documents two sites (one prehistoric habitation site and one historical ceramic cup fragment) within a one-mile radius of the alternative site. No previously recorded sites have been documented within the North of Desert Center Alternative.

Less than 1% of the North of Desert Center Alternative appears to have been subject to reliable pedestrian surveys. No cultural resources were documented during these surveys. Because so little of the alternative site has been surveyed, the lack of known sites is not a reliable indicator for the archaeological potential of the alternative site. As previously mentioned, a large portion of the alternative site is devoted to and disturbed by agricultural activities. The alternative site has high potential for encountering resources related to the DTC/C-AMA Cultural Landscape, and more specifically, to Camp Desert Center, an atypical and dispersed layout of facilities adjacent to the Desert Center Airfield and surrounding the community of Desert Center.

Assessment of Impacts and Discussion of Mitigation

For staff, Western, and BLM to more fully assess direct, indirect, and cumulative impacts for this proposed alternative, additional information would be needed. Similar to the proposed project, staff, Western, and BLM would make recommendations that the impacts of this alternative on cultural resources would have to be avoided or mitigated by means of data recovery, with specific modes of data recovery detailed in a MOA, to be negotiated and signed by the Western, BLM, the State Historic Preservation Officer, the Energy Commission, any Native American tribes or groups who opt to sign, and, possibly, the applicant.

CEQA/NEPA Level of Significance of Impacts

Staff, Western, and BLM assume that all construction impacts, direct, indirect, and cumulative, to all eligible and staff-assumed-eligible cultural resources located in the APE of this alternative would be substantial and adverse, and significant with respect to CEQA. Staff, Western and BLM also assume that these impacts would be reduced by the implementation of **CUL-1** through **CUL-12** and the mitigation measures outlined in the MOA, and would be less-than-significant with respect to CEQA. Staff, Western, and BLM would also provide mitigation measures for the appropriate treatment of potentially eligible archaeological resources discovered during construction of this alternative, should it be built, and these measures would reduce the alternative's impact on discovered Register-eligible archaeological resources to less than significant.

STATE ROUTE 62/RICE VALLEY ROAD GENERATION TIE LINE ALTERNATIVE

The State Route (SR) 62/Rice Valley Road Generation Tie Line Alternative would interconnect to Western's 161-kV/230-kV Parker-Blythe transmission line #2 at the same location as the proposed project generation tie line. This alternative generation tie line would exit the proposed solar facility at the northeast corner and follow SR 62 approximately 4.5 miles east to the junction of Rice Valley Road. It would then trend south to follow the unpaved Rice Valley Road for 4.0 miles to its juncture with the applicant's proposed new generation tie line alignment and continue southeast for 5.4 miles along the proposed alignment to Western's Parker-Blythe #2 transmission line. The SR 62/Rice Valley Road Generation Tie Line Alternative route is illustrated in **Alternatives Figure 3**.

The SR 62/Rice Valley Road Generation Tie Line Alternative is evaluated in this SA/DEIS because it would: (1) Avoid the permanent loss of 13.4 acres of foraging and cover habitat for plant and animal species, including the state and federally listed threatened desert tortoise and (2) Avoid the creation of a new 4.6 mile vehicle access route between the proposed solar facility and the proposed junction of the new transmission line access road with the existing Rice Valley road. The proposed new vehicle access route would necessitate additional enforcement and maintenance to prevent unauthorized off-road vehicle access, propagation of new, unauthorized vehicle routes, and consequent habitat damage, soil erosion, and vehicle disturbance.

Setting and Existing Conditions

All of the aspects of the setting and existing conditions as set out above for the proposed project are also pertinent to this alternative except the project description.

Cultural Resources Inventory

CH2MHILL's field survey for the proposed RSEP did not cover this alternative transmission alignment. However, since this alternative transmission line route travels through historic Camp Rice and follows the course of both the historic Colorado River Aqueduct and historic California SR 62, additional cultural resources are likely to be impacted. An additional pedestrian survey will be required in order for staff, Western and, BLM to properly assess impacts for this alternative.

Assessment of Impacts and Discussion of Mitigation

Staff, Western, and BLM would make recommendations that the impacts of this alternative, on cultural resources to be avoided or mitigated by means of data recovery, with specific modes of data recovery detailed in a MOA, be negotiated and signed by Western, BLM, the State Historic Preservation Officer, the Energy Commission, any Native American tribes or groups who opt to sign, and, possibly, the applicant.

CEQA/NEPA Level of Significance of Impacts

Staff, Western, and BLM would assume that all construction impacts, direct, indirect, and cumulative, to all eligible and staff-assumed-eligible cultural resources located in the APE of this alternative would be significant and adverse. Staff, Western, and BLM also assume that these impacts would be reduced to a less-than-significant level by the

implementation of **CUL-1** through **CUL-11** and the MOA. Staff, Western, and BLM would also provide mitigation measures for the appropriate treatment of potentially eligible archaeological resources discovered during construction of this alternative, should it be built, and these measures would reduce the alternative's impact on discovered Register-eligible archaeological resources to less than significant.

NO PROJECT/NO ACTION ALTERNATIVE

Under this alternative, the proposed Project would not be approved by the Energy Commission; BLM would not approve the transmission line application and would not amend the CDCA Plan; and Western would not approve the interconnection request. As a result, no solar energy project would be constructed on the project site, BLM would continue to manage the land encompassing the transmission line consistent with the existing land use designation in the CDCA Land Use Plan of 1980, as amended, and Western would continue to operate the Parker-Blythe Transmission Line under current conditions.

Because there would be no amendment to the CDCA Plan and no solar project approved for the site under this alternative, it is expected that the site would continue to remain in its existing condition, with no new structures or facilities constructed or operated on the site. As a result, none of the impacts (such as destruction of the Rice AAF and Camp Rice) from the proposed project would occur and none of the benefits of the proposed project (meaning the production of solar energy) would occur. In the absence of this project, other renewable energy project would have similar impacts in other locations.

COMPARISON OF ALTERNATIVES AND RECOMMENDATION OF LEAST IMPACT CULTURAL RESOURCES ALTERNATIVE

CH2MHILL's record search and field survey, and staff's review for the proposed RSEP, identified 26 eligible or assumed eligible resources. Because the Reduced Acreage Alternative would use the same ownership property boundary, the potential impact to the archaeological resources is the same for those two options.

The number of archaeological sites identified as subject to impacts from the SR62/Rice Valley Road Transmission Line Alternative is unknown, but likely greater than Project impacts, as it bisects Camp Rice.

The number of archaeological sites identified as subject to impacts from the North of Desert Center Alternative is unknown, thus no comparison can be made, and thus remains unanalyzed.

The number of archaeological sites identified as subject to impact from the No-Project/No-Action Alternative is 0.

From a comparison based on the number of archaeological sites that would be impacted, the No-Project/No-Action Alternative would have the least impact on cultural resources. If a project were to be built, of the analyzed options, the proposed Project and/or Reduced Acreage Alternative would have the least impacts on cultural resources.

NOTEWORTHY PUBLIC BENEFITS

Significant direct physical impacts to cultural resources often result in the complete destruction of the resource. Mitigation of these impacts frequently involves the collection of information (data recovery). This analysis and interpretation of the data collected through archaeology teaches us about the lives of historic people. This knowledge of American history enriches the lives of the general public. Therefore, although an important resource is lost forever, some of the information about that resource is retained. In the case of the history associated with Rice AAF, Camp Rice, and the DTC/C-AMA, the public's access to information would be significantly enhanced by implementation of the recommended mitigation measures/Conditions of Certification. This allows us to argue that these significant impacts can be mitigated to a less-than-significant level.

COMPLIANCE WITH LORS

The County of Riverside's General Plan has language promoting the general county-wide preservation of cultural resources. The programmatic agreement requires specific actions not just to promote but to effect historic preservation and mitigate impacts to all cultural resources in order to ensure NEPA and CEQA compliance. Consequently, if RSEP implements the recommended conditions of certification, its actions would be consistent with the general historic preservation goals of the County of Riverside.

Warren-Alquist Act (Pub. Resources Code § 25500 et seq.)

Pursuant to § 25529 of the Warren-Alquist Act, the Energy Commission shall require the establishment of an area for public use as a condition of certification of a facility proposed in an area of recreational, scenic, or historic value.

Staff concludes that this section of the Warren-Alquist Act is applicable on the basis that the project area has both historic and scenic values. Historic values are recognized within the project area and locale by the prior existence of Rice AAF, part of the greater DTC/C-AMA. The DTC/C-AMA can be thought of as an interconnected landscape of World War II training sites that are highly significant for their association with General George S. Patton and for their contributions to our understanding of how American soldiers were trained during World War II. Scenic values of the RSEP site are recognized considering the site is within large open areas of level topography and the absence of intervening landscape features. SR 62, north of the RSEP site, is part of a 143-mile segment of SR 62 eligible for State Scenic Highway designation. Called the "29 Palms Highway", the eligible scenic highway serves as the principal public access to Joshua Tree National Park roughly 25 aerial miles west of the project site. In addition, there are four BLM wilderness areas within 10 miles of the project site: Rice Valley, Turtle Mountain, Riverside Mountains and Palen/McCoy. (Please see the **Visual Resources and Land Use** sections of this document for more information.)

Selection Criteria

Staff used the following criteria as guidance for selecting an appropriate public use area:

- Would the public use area provide a specific and tangible benefit to the community?
- Are the public use area plans prepared or can they be readily prepared within the time frame of other plan preparations for the proposed RSEP project?
- Is the public use area environmental review and permitting underway or completed, or can it be integrated with the RSEP project?
- Would the public use area cause a public nuisance?
- Would the public use area be properly operated and maintained?
- Can the public use area that would be funded by the applicant be developed without dependency on additional funding sources?

Based on the above criteria, staff determined that a Historic Interpretive Area, developed immediately adjacent to the Project's Administration Area, with easy access from SR 62, would best meet the needs of the public, as well as the statutory requirement for a public use area.

Staff proposes Condition of Certification **CUL-11**, which would require the project owner to construct and maintain a Historic Interpretive Area, with visitor services, including parking, water, restrooms, and shade, appropriate to a desert environment. Although not specifically related to the interpretive value of the site, requirements for restrooms, drinking fountain, garbage cans, and shaded areas have been included to address relevant sanitary concerns and acknowledge the area's unique desert conditions. Providing self-closing containers and collection of refuse would minimize litter that could attract wildlife and invite increased predation on desert tortoise and other at-risk species. There are no existing restrooms or source of drinking water along SR62 for many miles in either direction. Restrooms would prevent the inappropriate use of the land surrounding the interpretive area and provide a means to properly contain and dispose of human waste. A properly maintained drinking fountain would provide public access to potable water in an environment where outside activities could contribute to dehydration and heat-related illness. Shaded areas would also reduce heat-related impacts.

CONDITIONS OF CERTIFICATION

Applicant Recommended Mitigation Measures

The applicant has provided the following recommendations for measures to mitigate adverse effects of the RSEP on the Rice AAF and Camp Rice.

Oral History

The applicant proposes to contact unit historians for information on units known to have trained at Rice AAF and Camp Rice and to identify living WWII veterans. These veterans would be requested to participate in an oral history interview. Transcriptions of interviews and video materials would be deposited in the General George Patton

Museum, the Special Collections Department at the University of California at Riverside, or other qualified repository.

Archival Research

The applicant proposes accessing archives of WWII historical record groups housed in the National Archives system and other sources, such as the General George Patton Museum, locating records associated with units or persons who trained at Rice AAF and Camp Rice. The end products of this effort would be a summary technical report of findings and an article to be published in a scholarly journal.

Site Mapping

The applicant proposes taking low-altitude, high-resolution aerial photographs of the Rice AAF and using these as a base map to outline the physical features, including foundations, refuse pits, stone alignments, and roads, visible from the air. The features should be annotated to indicate feature function as indicated on the 1942/1944 plan view. Sub-meter accuracy global positioning system devices would be used to record each of the major physical features in detail and generate a map using geographic information systems (GIS) on a topographic or aerial photographic base. The final product would be a detailed map of the associated features.

Public Education

The applicant proposes the creation of an internet site administered by Solar Reserve or other entity (such as BLM or General George Patton Museum) on which historical summaries, illustrations, and documents can be posted. In addition, the applicant proposes the development of a pamphlet and construction of an interpretive kiosk in Project land set aside as a public use area.

Public Access

The applicant proposes to establishing a Public Use Area consisting of a turnoff from SR 62, parking area for up to 8 vehicles, an interpretive kiosk protected by a shade structure that displays panels of text and illustrations (photographs, maps, and diagrams) that illustrate and interpret Rice AAF and Camp Rice as components of the larger DTC-AMA. This would contribute to meeting the provisions of the Warren-Alquist Act (California PRC 25529) as discussed in the **Compliance with LORS** subsection. Staff has identified some additional features of the public use area that it believes are necessary to complement those proposed by the applicant. Staff has incorporated the recommendations of the applicant into the Energy Commission proposed conditions of certification in a manner that would mitigate both project-specific and cumulative impacts to a less than significant level.

PROPOSED CONDITIONS OF CERTIFICATION

CUL-1 DESERT TRAINING CENTER CALIFORNIA-ARIZONA MANEUVER AREA CULTURAL LANDSCAPE (DTCCL) PROGRAM

The project owner shall contribute to a special fund set up by the Energy Commission and/or Western to finance the DTC/C-AMA Cultural Landscape Documentation and Possible NRHP Nomination Program (DTCCL Program) presented in the RSEP

SA/DEIS.

The amount of the contribution shall be \$22 per acre that the project encloses or otherwise disturbs. Any additional contingency contribution is not to exceed an amount totaling 20% of the original contribution. The contribution to the special fund may be made in installments, with the approval of the Compliance Project Manager (CPM), with the first installment to constitute 1/3 of the total original contribution amount.

If a project is not certified, a project owner does not build the project, or for any reason deemed acceptable by the CPM, a project owner does not participate in funding the DTCCCLProgram, the other project owner(s) may consult with the CPM to adjust the scale of the DTCCCL Program research activities to match available funding. A project owner that funds the DTCCCL Program and then withdraws shall be able to receive a refund of their contributions on a prorated basis.

Verification: Within two weeks (14 days) of the receipt of an invoice from the Energy Commission or BLM, the project owner shall contribute the entire amount of the required contribution or the first of three installments, equal to one-third of the total contribution amount, to the established funding vehicle for the Program. The delivery dates for the remaining installments shall be determined by the CPM, based on program requirements.

The project owner shall provide a copy of the notice of successful transfer of funds for any payment or installment to the DTCCCL fund to the CPM within 10 days of receipt.

CUL-2 CULTURAL RESOURCES PERSONNEL

Prior to the start of ground disturbance (includes preconstruction site mobilization and construction grading, boring, and trenching, as defined in the General Conditions for this project), the project owner shall obtain the services of a Cultural Resources Specialist (CRS) and one or more alternate CRSs, if alternates are needed. The CRS shall manage all monitoring, mitigation, curation, and reporting activities in accordance with the Conditions of Certification (Conditions).

The CRS may obtain the services of Cultural Resources Monitors (CRMs), as needed, to assist in monitoring, mitigation, and curation activities. The project owner shall ensure that the CRS implements the cultural resources conditions providing for data recovery from known historical resources and makes recommendations regarding the eligibility for listing in the California Register of Historical Resources (CRHR) of any cultural resources that are newly discovered or that may be affected in an unanticipated manner. No ground disturbance shall occur prior to Compliance Project Manager (CPM) approval of the CRS and alternates, unless such activities are specifically approved by the CPM. Approval of a CRS may be denied or revoked for reasons including, but not limited to, non-compliance on this or other Energy Commission projects.

Cultural Resources Specialist

The resumes for the CRS and alternate(s) shall include information demonstrating, to the satisfaction of the CPM, that their training and backgrounds conform to the U.S.

Secretary of Interior's Professional Qualifications Standards, as published in Title 36, Code of Federal Regulations, part 61. In addition, the CRS shall have the following qualifications:

1. A background in anthropology and prehistoric archaeology;
2. At least 10 years of archaeological resource mitigation and field experience, with at least 3 of those years in California; and
3. At least 3 years of experience in a decision-making capacity on cultural resources projects, with at least 1 of those years in California, and the appropriate training and experience to knowledgeably make recommendations regarding the significance of cultural resources.

The project owner shall ensure that the CRS obtains the services of a qualified historical archaeologist to conduct the research specified in **CUL-9**. The Project Historical Archaeologist's (PHA) training and background must meet the U.S. Secretary of Interior's Professional Qualifications Standards for historical archaeology, as published in Title 36, Code of Federal Regulations, part 61.

The resumes of the CRS, alternate CRS, and PHA shall include the names and telephone numbers of contacts familiar with the work of these persons on projects referenced in the resumes and demonstrate to the satisfaction of the CPM that these persons have the appropriate training and experience to undertake the required research. The project owner may name and hire the CRS, alternate CRS, and PHA prior to certification.

Field Crew Members and Cultural Resources Monitors

CRMs and field crew members shall have the following qualifications:

1. A B.S. or B.A. degree in anthropology, archaeology, historical archaeology, or a related field, and one year experience monitoring in California; or
2. An A.S. or A.A. degree in anthropology, archaeology, historical archaeology, or a related field, and four years experience monitoring in California; or
3. Enrollment in upper division classes pursuing a degree in the fields of anthropology, archaeology, historical archaeology, or a related field, and two years of monitoring experience in California.

Verification:

1. Preferably at least 120 days, but in any event no less than 75 days prior to the start of ground disturbance, the project owner shall submit the resumes for the CRS, the alternate CRS(s) if desired, and the PHA to the CPM for review and approval.
2. At least 65 days prior to the start of data recovery on known archaeological sites, the project owner shall confirm in writing to the CPM that the approved CRS (or alternate CRS) and PHA will be available for on-site work and are prepared to implement the cultural resources conditions of certification.

3. At least 10 days prior to a termination or release of the CRS, or within 10 days after the resignation of a CRS, the project owner shall submit the resume of the proposed new CRS to the CPM for review and approval. At the same time, the project owner shall also provide the AFC and all cultural resources documents, field notes, photographs, and other cultural resources materials generated by the project to the proposed new CRS. If no alternate CRS is available to assume the duties of the CRS, a monitor may temporarily serve in place of a CRS, for a maximum of three days, to allow ground disturbance to continue uninterrupted. If cultural resources are discovered, ground disturbance shall be halted until there is a CRS or alternate CRS to make a recommendation regarding significance.
4. At least 20 days prior to data recovery on known archaeological sites, the CRS shall provide a letter to the CPM for review and approval, naming anticipated field crew members for the project, providing resumes or other proof of qualifications, and attesting that the identified field crew members meet the minimum qualifications for cultural resources data recovery required by this Condition.
5. At least 20 days prior to ground disturbance, the CRS shall provide a letter to the CPM for review and approval, naming anticipated CRMs for the project providing resumes or other proof of qualifications, and attesting that the identified CRMs meet the minimum qualifications for cultural resources monitoring required by this Condition.
6. At least 5 days prior to additional CRMs beginning on-site duties during the project, the CRS shall provide letters to the CPM for review and approval, identifying the new CRMs, providing resumes or other proof of qualifications, and attesting to their qualifications.

CUL-3 PROJECT DOCUMENTATION FOR CULTURAL RESOURCES PERSONNEL

Prior to the start of ground disturbance, the project owner shall provide the CRS and PHA with copies of the AFC, data responses, confidential cultural resources documents, Staff Assessment (SA), and any subsequent revised or supplemental SA. The project owner shall also provide the CRS, PHA, and CPM with maps and drawings showing the footprints of the power plant, all linear facility routes, all access roads, and all laydown areas. Maps shall include the appropriate USGS quadrangles and maps at an appropriate scale (e.g., 1:2400 or 1" = 200') for plotting cultural features or materials. If the CRS requests enlargements or strip maps for linear facility routes, the project owner shall provide copies to the CRS and CPM. The CPM shall review map submittals and, in consultation with the CRS, approve those that are appropriate for use in cultural resources planning activities. No ground disturbance shall occur prior to CPM approval of maps and drawings, unless such activities are specifically approved by the CPM.

If construction of the project would proceed in phases, maps and drawings not previously provided shall be provided to the CRS, PHA, and CPM prior to the start of each phase. Written notice identifying the proposed schedule of each project phase shall be provided to the CRS and CPM.

Until ground disturbance is completed, the project construction manager shall provide

the CRS and CPM with a schedule of project activities for the following week, including the identification of area(s) where ground disturbance will occur. The project owner shall notify the CRS and CPM of any changes to the schedule of construction phases.

Verification:

1. Preferably at least 115 days, but in any event no less than 60 days prior to the start of ground disturbance, the project owner shall provide the CRS, PHA, and CPM with copies of the AFC, data responses, confidential cultural resources documents, the Staff Assessment (SA), and any revised or supplemental SAs. The project owner shall also provide the CRS, PHA, and CPM with the subject maps and drawings. Staff, in consultation with the CRS, and PHA, will review and approve maps and drawings as suitable for cultural resources monitoring and data recovery activities.
2. At least 15 days prior to the start of ground disturbance, if there are changes to any project-related footprint, the project owner shall provide revised maps and drawings for the changes to the CRS, PHA, and CPM.
3. At least 15 days prior to the start of each phase of a phased project, the project owner shall submit the appropriate maps and drawings, if not previously provided, to the CRS, PHA, and CPM.
4. Weekly, during ground disturbance, a schedule of anticipated following week's project activity shall be provided to the CRS and CPM by letter, e-mail, or fax.
5. Within 5 days of changing the scheduling of phases of a phased project, the project owner shall provide written notice of the changes to the CRS and CPM.

CUL-4 CULTURAL RESOURCES MONITORING AND MITIGATION PLAN

Prior to the start of ground disturbance, the project owner shall submit the Cultural Resources Monitoring and Mitigation Plan (CRMMP), as prepared by or under the direction of the CRS, with the contributions of the PHA, to the CPM for review and approval. The authors' name(s) shall appear on the title page of the CRMMP. The CRMMP shall specify the impact mitigation protocols for all known cultural resources and identify general and specific measures to minimize potential impacts to all other cultural resources, including those discovered during construction. Implementation of the CRMMP shall be the responsibility of the CRS and the project owner. Copies of the CRMMP shall reside with the CRS, alternate CRS, PHA, each CRM, and the project owner's on-site construction manager. No ground disturbance shall occur prior to CPM approval of the CRMMP, unless such activities are specifically approved by the CPM. Prior to certification, the project owner may have the CRS, alternate CRS, , and PHA complete and submit the CRMMP to the CPM for review and approval, except for those portions to be contributed by the DTCCCL programs.

The CRMMP shall include, but is not limited to, the elements and measures listed below.

1. The following statement shall be included in the Introduction: "Any discussion, summary, or paraphrasing of the Conditions of Certification in this CRMMP is

intended as general guidance and as an aid to the user in understanding the Conditions and their implementation. The conditions, as written in the Commission Decision, shall supersede any summarization, description, or interpretation of the conditions in the CRMMP. The Cultural Resources Conditions of Certification from the Commission Decision are contained in Appendix A.”

2. The duties of the CRS shall be fully discussed, including coordination duties with respect to the completion of the Desert Training Center California-Arizona Maneuver Area Cultural Landscape (DTCCCL) documentation and possible NRHP nomination program, and oversight/management duties with respect to site evaluation, data collection, monitoring, and reporting at both known prehistoric and historic-period archaeological sites and any CRHR-eligible (as determined by the CPM) prehistoric and historic-period archaeological sites discovered during construction.
3. A general research design shall be developed that:
 - a. Charts a timeline of all research activities, including those coordinated under the DTCCCL documentation and possible NRHP nomination program;
 - b. Recapitulates the existing historic contexts developed in the DTCCCL historic context and adds to these the additional context of the non-military, historic-period occupation and use of the Rice Valley, to create a comprehensive historic context for the RSEP vicinity;
 - c. Poses archaeological research questions and testable hypotheses specifically applicable to the archaeological resource types known for Rice Valley, based on the research questions developed under the DTCCCL research and on the archaeological and historical literature pertinent to Rice Valley; and
 - d. Clearly articulates why it is in the public interest to address the research questions that it poses.
4. Protocols, consistent with the guidance provided in **CUL-9**, shall be specified for the treatment of known and newly discovered prehistoric and historic-period archaeological resource types.
5. Artifact collection, retention/disposal, and curation policies shall be discussed, as related to the research questions formulated in the research design. These policies shall apply to cultural resources materials and documentation resulting from evaluation and data recovery at both known prehistoric and historic-period archaeological sites and any CRHR- or NRHP-eligible (as determined by the CPM) prehistoric and historic-period archaeological sites discovered during construction. A prescriptive treatment plan may be included in the CRMMP for limited data types.
6. The implementation sequence and the estimated time frames needed to accomplish all project-related tasks during the ground-disturbance and post-ground-disturbance analysis phases of the project shall be specified.
7. Person(s) expected to perform each of the tasks, their responsibilities, and the reporting relationships between project construction management and the mitigation

and monitoring team shall be identified.

8. The manner in which Native American observers or monitors will be included, in addition to their roles in the activities required under CUL-1; the procedures to be used to select them; and their roles and responsibilities shall be described.
9. All impact-avoidance measures (such as flagging or fencing) to prohibit or otherwise restrict access to sensitive resource areas that are to be avoided during ground disturbance, construction, and/or operation shall be described. Any areas where these measures are to be implemented shall be identified. The description shall address how these measures would be implemented prior to the start of ground disturbance and how long they would be needed to protect the resources from project-related impacts.
10. The commitment to record on Department of Parks and Recreation (DPR) 523 forms, to map, and to photograph all encountered cultural resources over 50 years of age shall be stated. In addition, the commitment to curate all archaeological materials retained as a result of the archaeological investigations (survey, testing, data recovery), in accordance with the California State Historical Resources Commission's Guidelines for the Curation of Archaeological Collections, into a retrievable storage collection in a public repository or museum shall be stated.
11. The commitment of the project owner to pay all curation fees for artifacts recovered and for related documentation produced during cultural resources investigations conducted for the project shall be stated. The project owner shall identify a curation facility that could accept cultural resources materials resulting from RSEP cultural resources investigations.
12. The CRS shall attest to having access to equipment and supplies necessary for site mapping, photography, and recovery of all cultural resource materials (that cannot be treated prescriptively) from known CRHR-eligible archaeological sites and from CRHR-eligible sites that are encountered during ground disturbance .
13. The contents, format, and review and approval process of the final Cultural Resource Report (CRR) shall be described.

Verification:

1. Preferably at least 90 days, but in any event no less than 30 days prior to the start of ground disturbance, the project owner shall submit the CRMMP to the CPM for review and approval.
2. At least 20 days prior to the start of ground disturbance, in a letter to the CPM, the project owner shall agree to pay curation fees for any materials generated or collected as a result of the archaeological investigations (survey, testing, data recovery).
3. At least 30 days prior to the initiation of ground disturbance, the project owner shall provide to the CPM a copy of a letter from a curation facility that meets the standards stated in the California State Historical Resources Commission's Guidelines for the Curation of Archaeological Collections, stating the facility's

willingness and ability to receive the materials generated by RSEP cultural resources activities and requiring curation. Any agreements concerning curation will be retained and available for audit for the life of the project.

CUL-5 CULTURAL RESOURCES REPORT (CRR)

The project owner shall submit the final Cultural Resources Report (CRR) to the CPM for review and approval and to Western's archaeologist for review and comment. The final CRR shall be written by or under the direction of the CRS. The final CRR shall report on all field activities including dates, times and locations, results, samplings, and analyses. All survey reports, revised and final Department of Parks and Recreation (DPR) 523 forms, data recovery reports, and any additional research reports not previously submitted to the California Historical Resource Information System (CHRIS) and the State Historic Preservation Officer (SHPO) shall be included as appendices to the final CRR.

If the project owner requests a suspension of ground disturbance and/or construction activities, then a draft CRR that covers all cultural resources activities associated with the project shall be prepared by the CRS and submitted to the CPM and to Western's archaeologist for review and approval on the same day as the suspension/extension request. The draft CRR shall be retained at the project site in a secure facility until ground disturbance and/or construction resumes or the project is withdrawn. If the project is withdrawn, then a final CRR shall be submitted to the CPM for review and approval at the same time as the withdrawal request.

Verification:

1. Within 30 days after requesting a suspension of construction activities, the project owner shall submit a draft CRR to the CPM for review and approval.
2. Within 180 days after completion of ground disturbance (including landscaping), the project owner shall submit the final CRR to the CPM for review and approval and to the BLM Palm Springs archaeologist and Western's archaeologist for review and comment. If any reports have previously been sent to the CHRIS, then receipt letters from the CHRIS or other verification of receipt shall be included in an appendix.
3. Within 10 days after the CPM and Western's archaeologist approve the CRR, the project owner shall provide documentation to the CPM confirming that copies of the final CRR have been provided to the SHPO, the CHRIS, the curating institution, if archaeological materials were collected, and to the Tribal Chairpersons of any Native American groups requesting copies of project-related reports.

CUL-6 WORKER ENVIRONMENTAL AWARENESS PROGRAM (WEAP)

Prior to and for the duration of ground disturbance, the project owner shall provide Worker Environmental Awareness Program (WEAP) training to all new workers within their first week of employment at the project site, along the linear facilities routes, and at laydown areas, roads, and other ancillary areas. The training shall be prepared by the CRS, may be conducted by any member of the archaeological team, and may be presented in the form of a video. The CRS shall be available (by telephone or in person) to answer questions posed by employees. The training may be discontinued when

ground disturbance is completed or suspended, but must be resumed when ground disturbance, such as landscaping, resumes.

The training shall include:

1. A discussion of applicable laws and penalties under the law;
2. Samples or visuals of artifacts that might be found in the project vicinity;
3. A discussion of what such artifacts may look like when partially buried, or wholly buried and then freshly exposed;
4. A discussion of what prehistoric and historical archaeological deposits look like at the surface and when exposed during construction, and the range of variation in the appearance of such deposits;
5. Instruction that the CRS, alternate CRS, and CRMs have the authority to halt ground disturbance in the area of a discovery to an extent sufficient to ensure that the resource is protected from further impacts, as determined by the CRS;
6. Instruction that employees are to halt work on their own in the vicinity of a potential cultural resources discovery and shall contact their supervisor and the CRS or CRM, and that redirection of work would be determined by the construction supervisor and the CRS;
7. An informational brochure that identifies reporting procedures in the event of a discovery;
8. An acknowledgement form signed by each worker indicating that they have received the training; and
9. A sticker that shall be placed on hard hats indicating that environmental training has been completed.
10. No ground disturbance shall occur prior to implementation of the WEAP program, unless such activities are specifically approved by the CPM.

Verification:

1. At least 30 days prior to the beginning of ground disturbance, the CRS shall provide the training program draft text and graphics and the informational brochure to the CPM for review and approval.
2. At least 15 days prior to the beginning of ground disturbance, the CPM will provide the project owner with a WEAP Training Acknowledgement form for each WEAP trained worker to sign.
3. Monthly, until ground disturbance is completed, the project owner shall provide, in the Monthly Compliance Report (MCR), the WEAP Training Acknowledgement forms of workers who have completed the training in the prior month and a running total of all persons who have completed training to date.

CUL-7 CONSTRUCTION MONITORING PROGRAM

The project owner shall ensure that the CRS, alternate CRS, or CRMs monitor, full time, all ground disturbance, to prevent construction impacts to undiscovered resources and to ensure that known resources are not impacted in an unanticipated manner,.

Full-time archaeological monitoring for this project shall include the archaeological monitoring of ground-disturbing activities by approved CRS or CPM in the areas specified, for as long as the activities are ongoing. Where excavation equipment is actively removing dirt and hauling the excavated material farther than fifty feet from the location of active excavation, full-time archaeological monitoring shall require at least two monitors per excavation area. In this circumstance, one monitor shall observe the location of active excavation and a second monitor shall inspect the dumped material. For excavation areas where the excavated material is dumped no farther than fifty feet from the location of active excavation, one monitor shall both observe the location of active excavation and inspect the dumped material. The research design in the CRMMMP shall govern the collection, treatment, retention/disposal, and curation of any archaeological materials encountered.

On forms provided by the CPM, CRMs shall keep a daily log of any monitoring and other cultural resources activities and any instances of noncompliance with the Conditions and/or applicable LORS. Copies of the daily monitoring logs shall be provided by the CRS to the CPM, if requested by the CPM. From these logs, the CRS shall compile a monthly monitoring summary report to be included in the MCR. If there are no monitoring activities, the summary report shall specify why monitoring has been suspended.

The CRS or alternate CRS shall report daily to the CPM on the status of the project's cultural resources-related activities, unless reducing or ending daily reporting is requested by the CRS and approved by the CPM. In the event that the CRS believes that the current level of monitoring is not appropriate in certain locations, a letter or e-mail detailing the justification for changing the level of monitoring shall be provided to the CPM for review and approval prior to any change in the level of monitoring. The CRS, at his or her discretion, or at the request of the CPM, may informally discuss cultural resources monitoring and mitigation activities with Energy Commission technical staff.

Cultural resources monitoring activities are the responsibility of the CRS. Any interference with monitoring activities, removal of a monitor from duties assigned by the CRS, or direction to a monitor to relocate monitoring activities by anyone other than the CRS shall be considered non-compliance with these Conditions.

Upon becoming aware of any incidents of non-compliance with the Conditions and/or applicable LORS, the CRS and/or the project owner shall notify the CPM by telephone or e-mail within 24 hours. The CRS shall also recommend corrective action to resolve the problem or achieve compliance with the Conditions. When the issue is resolved, the CRS shall write a report describing the issue, the resolution of the issue, and the effectiveness of the resolution measures. This report shall be provided in the next MCR for the review of the CPM.

Verification:

1. At least 30 days prior to the start of ground disturbance, the CPM shall provide to the CRS an electronic copy of a form to be used as a daily monitoring log.
2. Monthly, while monitoring is on-going, the project owner shall include, in each MCR, a copy of the monthly summary report of cultural resources-related monitoring prepared by the CRS and shall attach any new DPR 523A forms completed for finds treated prescriptively, as specified in the CRMMP.
3. At least 24 hours prior to implementing a proposed change in monitoring level, the project owner shall submit to the CPM, for review and approval, a letter or e-mail (or some other form of communication acceptable to the CPM) detailing the CRS's justification for changing the monitoring level.
4. Daily, as long as no cultural resources are found, the CRS shall provide a statement that "no cultural resources over 50 years of age were discovered" to the CPM as an e-mail or in some other form of communication acceptable to the CPM.
6. At least 24 hours prior to reducing or ending daily reporting, the project owner shall submit to the CPM, for review and approval, a letter or e-mail (or some other form of communication acceptable to the CPM) detailing the CRS's justification for reducing or ending daily reporting.
7. No later than 30 days following the discovery of any Native American cultural materials, the project owner shall submit, to the CPM, copies of the information transmittal letters sent to the Chairpersons of the Native American tribes or groups who requested the information. Additionally, the project owner shall submit to the CPM copies of letters of transmittal for all subsequent responses to Native American requests for notification, consultation, and reports and records.
8. The project owner shall submit to the CPM copies of any comments or information provided by Native Americans in response to the project owner's transmittals of information within 15 days of receipt,

CUL-8 AUTHORITY TO HALT CONSTRUCTION; TREATMENT OF DISCOVERIES

The project owner shall grant authority to halt ground disturbance to the CRS, alternate CRS, PHA, and the CRMs in the event of a discovery. Redirection of ground disturbance shall be accomplished under the direction of the construction supervisor in consultation with the CRS.

In the event that a cultural resource over 50 years of age is found (or if younger, determined exceptionally significant by the CPM), or impacts to such a resource can be anticipated, ground disturbance shall be halted or redirected in the immediate vicinity of the discovery sufficient to ensure that the resource is protected from further impacts. Monitoring and daily reporting, as provided in other conditions, shall continue during the project's ground-disturbing activities elsewhere. The halting or redirection of ground

disturbance shall remain in effect until the CRS has visited the discovery, and all of the following have occurred:

1. The CRS has notified the project owner and the CPM has been notified within 24 hours of the discovery, or by Monday morning if the cultural resources discovery occurs between 8:00 AM on Friday and 8:00 AM on Sunday morning, including a description of the discovery (or changes in character or attributes), the action taken (i.e., work stoppage or redirection), a recommendation of CRHR eligibility, and recommendations for data recovery from any cultural resources discoveries, whether or not a determination of CRHR eligibility has been made.
2. If the discovery would be of interest to Native Americans, the CRS has notified all Native American groups that expressed a desire to be notified in the event of such a discovery.
3. The CRS has completed field notes, measurements, and photography for a DPR 523 "Primary" form. Unless the find can be treated prescriptively, as specified in the CRMMP, the "Description" entry of the DPR 523 "Primary" form shall include a recommendation on the CRHR eligibility of the discovery. The project owner shall submit completed forms to the CPM.
4. The CRS, the project owner, and the CPM have conferred, and the CPM has concurred with the recommended eligibility of the discovery and approved the CRS's proposed data recovery plan, if any, including the curation of the artifacts, or other appropriate mitigation; and any necessary data recovery and mitigation have been completed.

Verification:

1. At least 30 days prior to the start of ground disturbance, the project owner shall provide the CPM and CRS with a letter confirming that the CRS, alternate CRS, PHA, and CRMs have the authority to halt ground disturbance in the vicinity of a cultural resources discovery, and that the project owner shall ensure that the CRS notifies the CPM within 24 hours of a discovery, or by Monday morning if the cultural resources discovery occurs between 8:00 AM on Friday and 8:00 AM on Sunday morning.
2. Within 48 hours of the discovery of a resource of interest to Native Americans, the project owner shall ensure that the CRS notifies all Native American groups that expressed a desire to be notified in the event of such a discovery.
3. Unless the discovery can be treated prescriptively, as specified in the CRMMP, completed DPR 523 forms for resources newly discovered during ground disturbance shall be submitted to the CPM for review and approval no later than 24 hours following the notification of the CPM, or 48 hours following the completion of data recordation/recovery, whichever the CRS decides is more appropriate for the subject cultural resource.

CUL-9 DATA RECOVERY FOR RICE ARMY AIR FIELD AND CAMP RICE FEATURES

Prior to the start of ground disturbance, the project owner shall ensure that records for

all 298 historic-period features be upgraded. The focus of the recordation upgrade is to recover any additional data associated with these features before they are destroyed during construction. A plan shall specify in detail the location recordation equipment and methods to be used and describe any anticipated post-processing of the data. The project owner shall then ensure that the CRS, the PHA, and/or archaeological team members implement the plan, if allowed by the CPM, which shall include, but is not limited to the following tasks:

1. The project owner shall hire a PHA with the qualifications described in **CUL-2** to supervise the field work.
2. The project owner shall ensure that, prior to beginning the field work, the PHA and all field crew members are trained by the DTCCCL Historical Archaeologist, or equivalent qualified person approved by the CPM and hired by the project owner should the DTCCCL Historical Archaeologist not be available, to identify the specific landform for each site; in the identification, analysis and interpretation of the artifacts, environmental modifications, and trash disposal patterns associated with the early phases of WWII land-based U.S. army activities, as researched and detailed by the DTCCCL PI-Historian and the DTCCCL Historical Archaeologist.
3. The project owner shall ensure that, prior to beginning the field work, the field crew members are also trained in the consistent and accurate identification of the full range of late nineteenth and early-to-mid-twentieth-century can, bottle, and ceramic diagnostic traits.
4. The project owner shall ensure that the original site map shall be updated to include at minimum: landform features such as small drainages, any man-made features, the limits of any artifact concentrations and features (previously known and newly found in the metal detector survey), using location recordation equipment that has the latest technology with sub-meter accuracy (such as UTM 11 North or California Teale Albers).
5. The project owner shall ensure that a detailed in-field analysis of all artifacts shall be completed, documenting the measurements and the types of seams and closures for each bottle, and the measurements, seams, closure, and opening method for all cans. Photographs shall be taken of maker's marks on bottles, any text or designs on bottles and cans, and of decorative patterns and maker's marks on ceramics. Artifacts shall not be collected.
6. The project owner shall ensure a systematic metal detector survey be completed at each site, and that each "hit" is investigated. All artifacts and features thus found must be mapped, measured, photographed, and fully described in writing.
7. The project owner shall ensure that all structures are mapped, measured, photographed, and fully described in writing, and that all associated features having subsurface elements are excavated by a qualified historical archaeologist. All features and contents must be mapped, measured, photographed, and fully described in writing.
8. The project owner shall ensure that the details of what is found at each site shall be

presented in a letter report from the CRS or PHA which shall serve as a preliminary report, that details what was found at each site, as follows:

- a. Letter reports may address one site or multiple sites depending on the needs of the CRS; and
 - b. The letter report shall be a concise document that provides a description of the schedule and methods used in the field effort, a preliminary tally of the numbers and types of features and deposits that were found, a discussion of the potential range of error for that tally, and a map showing the location of collection and/or excavation units, including topographic contours and the site landforms.
 - c. The letter report shall make a recommendation on whether each site is a contributor to the DTTCL.
9. The project owner shall ensure that the data collected from the field work shall be provided to the DTCCCL Historical Archaeologist to assist in the determination of which, if any, of the historic-period sites are contributing elements to the DTCCCL.
10. The project owner shall ensure that the PHA analyzes all recovered data and writes or supervises the writing of a comprehensive final report. This report shall be included in the CRR (**CUL-5**). Relevant portions of the information gathered shall be included in the possible NRHP nomination for the DTCCCL (funded by **CUL-1**).

Verification:

1. At least 90 days prior to ground disturbance, the project owner shall notify the CPM that mapping and upgraded in-field artifact analysis has ensued.
2. Within one week of completing data recovery at a site, the project owner shall submit to the CPM for review and approval a letter report written by the CRS, evidencing that the field portion of data recovery at each site has been completed. When the CPM approves the letter report, ground disturbance may begin at the site location(s) that are the subject of the letter report.

CUL-10 COMPLIANCE COORDINATION WITH FEDERAL SECTION 106 MOA

If stipulations in the RSEP Section 106 Memorandum of Agreement (MOA), should such a document be prepared and executed, conflict in a mutually exclusive manner with or precisely duplicate the conditions of certification in the Energy Commission Decision, the MOA provisions shall take precedence. Where provisions for the implementation of historic preservation treatments in the conditions of certification are in addition to or exceed such provisions in the MOA, the applicant shall implement treatment in a manner that fulfills both the provisions of the MOA and the conditions of certification. Where the applicant believes that a mutually exclusive conflict exists between these conditions and the provisions in the MOA, or that the said conditions and provisions appear to require a precisely duplicative effort, the applicant shall submit, for the review and approval of the CPM, formal correspondence that states the applicant's determination that such a conflict or effort exists and provides evidentiary support for that determination. Where provisions in the conditions of compliance appear to augment or exceed the provisions in the MOA, the project owner shall coordinate historic preservation treatment with the CPM. Such coordination may, at the discretion of the

applicant, be on a formal or informal basis. However, the CPM shall make the final determination of the consistency of project activities with Energy Commission conditions of compliance.

Verification:

1. Prior to the implementation of any historic preservation treatments in these conditions that may conflict in a mutually exclusive manner with any analogous treatments that a Federal MOA may provide or that may precisely duplicate such analogous treatments, the project owner shall consult with the CPM concerning any such conflicts and provide, for the review and approval of the CPM, formal correspondence that relates the outcome of said consultation, states the applicant's determination that a mutually exclusive conflict or precisely duplicative effort exists, and provides evidentiary support for that determination. The applicant shall not proceed with the implementation of any historic preservation treatments that are subject to consultation under this condition until the CPM approves the applicant's determination thereon.

CUL-11: PUBLIC ACCESS TO HISTORIC FEATURES

Prior to the start of construction, the project owner shall provide conceptual plans for the Historic Interpretive Area to the CPM for review and approval. The plans shall also identify existing historic features of Rice AAF and Camp Rice that would be protected from disturbance during construction and preserved in accordance with the MOA. Prior to commercial operation of RSEP, the project owner shall provide the final plans for the Historic Interpretive Area to Western, BLM, and Riverside County for review and comment, and to the CPM, for review and approval, that would illustrate and interpret Rice AAF and Camp Rice as components of the larger DTC/C-AMA. Construction of the Historic Interpretive Area shall be complete prior to the start of commercial operations. The project owner's plans for the Historic Interpretive Area may be coordinated with Caltrans and Riverside County, and shall be developed in a manner that does not compromise site or public safety or security.

The Historic Interpretive Area shall include and make accessible to the public the following features:

1. An encroachment off SR 62 (proposed Fire Access road encroachment) to the Historic Interpretive Area and vehicle parking area, consistent with Riverside County and the Americans with Disabilities Act (ADA) requirements parking requirements;
2. An interpretive kiosk protected by a shade structure that displays panels of text and illustrations (e.g. photographs, maps, and diagrams) that illustrate and interpret Rice AAF and Camp Rice as components of the larger DTC/C-AMA;
3. Identification of existing historic features of Rice AAF, adjacent to the kiosk, with signage and interpretive information along an ADA-accessible walking trail;
4. A shade-covered area, with minimum of two picnic tables and benches;
5. Self-closing, wildlife-resistant trash cans;

6. A two-stall, ADA-accessible, contained restroom facility; and
7. A drinking fountain.

Verification:

1. At least 30 days prior to the start of construction, the project owner shall submit conceptual plans for the Historic Interpretive Area to Western, BLM, and Riverside County for review and comment, and to the CPM for review and approval. The plan shall identify existing historic features of Rice AAF and Camp Rice that would be protected from disturbance during construction and preserved in accordance with the MOA.
2. No later than one year following commencement of RSEP construction, the project owner shall submit final plans for the Historic Interpretive Area to Western, BLM, and Riverside County for review and comment, and to the CPM for review and approval.
3. At least 30 days prior to RSEP commercial operation, the project owner shall complete construction of the Historic Interpretive Area and obtain approval from the CPM that the Historic Interpretive Area meets the requirements of this condition. The Historic Interpretive Area shall be open to the public within 10 days from the start of commercial operations and shall be maintained for the life of the project.

In each Annual Compliance Report, the project owner shall provide a summary of the following:

1. Estimated public visitation to the Historic Interpretive Area;
2. Any issues associated with operating and maintenance;
3. Proposed maintenance and improvements, and a schedule for completion;
4. A log of all completed maintenance and improvements to the Historic Interpretive Area from the start of RSEP commercial operation to the present day.

CUL-12 FLAG AND AVOID

Resources within the Warren-Alquist Public Use Area (in the northwestern corner of the main facility footprint) will be preserved through avoidance. Previously recorded resources along Western's Parker Dam-Blythe Transmission Line No. 2, subject to possible project impacts, shall be revisited prior to construction. In the event that new resources are discovered during construction or previously recorded resources would be additionally affected, where impacts can be reduced or avoided, the project owner shall:

1. Ensure that a CRS, alternate CRS or CRM re-establish the boundary of each site, add a 10-meter-wide buffer around the periphery of each site boundary, and flag the resulting space in a conspicuous manner;
2. Ensure that a CRM enforces avoidance of the flagged areas during RSEP construction; and

3. Ensure, after completion of construction, boundary markings around each site and buffer are removed so as not to attract vandals.
4. Site records for previously documented resources shall be updated.

Verification:

Within 90 days of transmission line construction, the project owner shall submit for CPM review and approval, site record updates of resources subject to possible impacts.

Within 90 days of the completion of plant construction, the project owner shall submit for CPM review and approval a letter, with photograph and maps, evidencing the removal of boundary markings.

CONCLUSIONS AND RECOMMENDATIONS

With respect to CEQA, staff¹⁸ concludes that the proposed Rice Solar Energy Project (RSEP) would have significant direct impacts to the features and artifact concentrations associated with the historic Rice Army Airfield (Rice AAF)¹⁹ and the western periphery of Camp Rice (CA-SBA-10526H), as well as potential direct impacts to 23 other eligible or assumed eligible archaeological sites.

Staff finds that the RSEP construction impacts, when combined with impacts from the past, present, and reasonably foreseeable projects, contribute in a small but significant way to the cumulatively considerable adverse impacts to cultural resources at the regional level. Staff recommends the adoption of **CUL-1**, which would reduce RSEP's cumulative impacts to a less than significant level. The program established by this condition of certification would define, document, and nominate the Desert Training Center Cultural Landscape to both the National Register of Historic Places (NRHP) and the California Register of Historical Resources (CRHR). Other solar projects in the southern desert, including Blythe Solar Power Project, Palen Solar Power Project, and Genesis Solar Energy Project, are also included in this regional effort.

Staff also recommends that the Energy Commission adopt Conditions of Certification **CUL-2** through **CUL-12**, to mitigate RSEP's project-specific cultural resource impacts. These conditions of certification include the following:

- **CUL-2** identifies the positions and qualifications of personnel responsible for implementing and monitoring the Energy Commission cultural resource conditions of certification .
- **CUL-3** specifies the information and project documentation to be supplied by the project owner.
- **CUL-4** requires the preparation and implementation of a Cultural Resources Monitoring and Mitigation Plan (CRMMP), which would structure and govern the implementation of the broader treatment program.
- **CUL-5** would require the preparation of a final Cultural Resources Report (CRR) that

¹⁸ "Staff" means Energy Commission staff unless otherwise indicated.

¹⁹ No primary number or trinomial has been assigned yet to this resource.

would analyze, interpret, and document the results of all field activities and research findings for the RSEP cultural resources management program.

- **CUL-6** would require training of all project personnel to identify, avoid, protect, and provide appropriate notice of potential cultural resources in the project construction area.
- **CUL-7** and **CUL-89** would provide construction monitoring and cultural resources discovery protocols.
- **CUL-9** identifies data recovery protocols for the Rice AAF/Camp Rice.
- **CUL-10** identifies a process for resolving any inconsistencies in impact significance and mitigation requirements, as it would relate to stipulations within an Energy Commission/Western/BLM Memorandum of Agreement (MOA), Section 106 consultation. The MOA may be included in the Western Final Environmental Impact Statement (FEIS) for the RSEP right-of-way application or be released as a separate document. However, the Energy Commission's Staff Assessment (SA) will be published in advance of the FEIS and completion of the MOA. Therefore, there is the possibility that staff's recommended conditions of certification may conflict with the mitigation measures or monitoring protocols identified in this document. A revised or supplemental SA may be needed to identify or clarify any differences between the energy Commission conditions of certification and proposed Federal cultural resources mitigation.
- **CUL-11** would require construction of a public use area on the project site as partial mitigation for the impacts to historic and scenic values of the area, consistent with the requirements of Section 25529 of the Warren-Alquist Act.
- **CUL-12** would ensure previously documented and newly discovered cultural resources within Western's Parker Dam-Blythe Transmission Line No. 2 corridor and Historic Interpretive Area are flagged and avoided during proposed construction.

Implementation of the proposed conditions of certification included in this Cultural Resources section would satisfy the Energy Commission's responsibility to comply with CEQA, ensure consistency with the applicable LORS, and reduce impacts to cultural resources to a less than significant level. The identification of relevant and reasonable mitigation measures also conforms to NEPA requirements for the BLM/Western analysis that can be considered in the Record of Decision (ROD).

GLOSSARY

CULTURAL RESOURCES ACRONYM GLOSSARY

AD	After the Birth of Christ
AFC	Application for Certification
ARMR	Archaeological Resource Management Report
BC	Before the Birth of Christ
RSEP	the proposed project, Palen Solar Power Project
CEQA	California Environmental Quality Act
CHRIS	California Historical Resources Information System
Conditions	California Energy Commission Conditions of Certification
CRHR	California Register of Historical Resources
CRM	Cultural Resources Monitor
CRMMP	Cultural Resources Monitoring and Mitigation Plan
CRR	Cultural Resource Report
CRS	Cultural Resources Specialist
DEIS	Draft Environmental Impact Statement
DPR 523	Department of Parks and Recreation cultural resource inventory form
EIC	Eastern Information Center (CHRIS), University of California, Riverside
FAR	Fire-Affected Rock
LORS	laws, ordinances, regulations, and standards
MCR	Monthly Compliance Report
MLD	Most Likely Descendent
NAHC	Native American Heritage Commission
NEPA	National Environmental Protection Act
NHPA	National Historic Preservation Act

NRHP	National Register of Historic Places
OHP	Office of Historic Preservation
PAA	Project Area of Analysis consists of the project site (see below) plus what additional areas staff defines for each project that are necessary for the analysis of the cultural resources that the project may impact.
Project Site	The bounded area(s) identified by the applicant as the area(s) within which they propose to build the project.
SHPO	State Historic Preservation Officer
Staff	Energy Commission cultural resources technical staff
SA	Staff Assessment
WEAP	Worker Environmental Awareness Program

THIS PAGE IS INTENTIONALLY LEFT BLANK

CULTURAL RESOURCES APPENDIX A

**Cultural Resources Table 3
Previously Recorded Sites within the Study Area (Records Search Limits)**

Site	Prehistoric/ Historic	Associated Project Component	Description	Within APE
RIV-872	P	P-B T/L #2*	Trail	yes
SBR-8872	P	P-B T/L #2	Trail	yes
SBR-8873	P	P-B T/L #2P	Trail	yes
SBR-8874	P	P-B T/L #2	Trails	yes
SBR-8875	P	P-B T/L #2	Trail	yes
RIV-160	P	P-B T/L #2	Trail and quarry	yes
RIV-3418	P	P-B T/L #2	Lithic Scatter, quarry	yes
RIV-5985T	P	P-B T/L #2	Trail	yes
RIV-1135	P	P-B T/L #2	Quarry	yes
RIV-5984T	P	P-B T/L #2	Trail	yes
SBR-1498	P	P-B T/L #2	Trail	yes
SBR-1499	P	P-B T/L #2	Trail	yes
SBR-1500	P	P-B T/L #2	Sparse lithic scatter with chipping stations	yes
SBR-1506	P	P-B T/L #2	Trail and flake scatter	yes
SBR-1507	P	P-B T/L #2	Ceramics	yes
SBR-1508	P	P-B T/L #2	Trail with lithic	yes
SBR-1511	P	P-B T/L #2	Quarry area	yes
SBR-1514	P	P-B T/L #2	Lithic quarry area , sparse lithic scatter	yes
SBR-1521	P	P-B T/L #2	Lithic quarry area	yes
SBR-1522	P	P-B T/L #2	Lithic quarry area	yes
SBR-1523	P	P-B T/L #2	Lithic quarry area	yes

Site	Prehistoric/ Historic	Associated Project Component	Description	Within APE
SBR-1524	P	P-B T/L #2	Lithic quarry, sparse lithic scatter; trail, lithics rock art	yes
SBR-1525	P	P-B T/L #2	Quarry	yes
SBR-2525	P	P-B T/L #2	Geoglyph	yes
SBR-8004	P	P-B T/L #2	Trail	yes
SBR-8018	P	P-B T/L #2	Lithics	yes
SBR-8025	P	P-B T/L #2	Lithics	yes
SBR-8877	P	P-B T/L #2	Trail, pot drop	yes
SBR-8878	P	P-B T/L #2	Trail, pot drop	yes
SBR-8879	P	P-B T/L #2	Lithics, 2 chipping stations	yes
SBR-8880	P	P-B T/L #2	Lithics with 3 concentrations	yes
SBR-8881	P	P-B T/L #2	Lithic scatter	yes
SBR-8882	P	P-B T/L #2	Lithics with 4+ concentrations	yes
SBR-8883	P	P-B T/L #2	Sparse lithic scatter	yes
SBR-8884	P	P-B T/L #2	Extensive lithic scatter	yes
SBR-8885	P	P-B T/L #2	Sparse lithic scatter with 3+ c.s.*	yes
SBR-8886	P	P-B T/L #2	Small chipping stations and lithic scatter	yes
SBR-8887	P	P-B T/L #2	Chipping station	yes
SBR-8888	P	P-B T/L #2	Lithic scatter with two c.s.	yes
SBR-8889	P	P-B T/L #2	Trails with lithic scatter, one c. s.	yes
SBR-8890	P	P-B T/L #2	Lithic scatter with 4 c.s.	yes
SBR-8892	P	P-B T/L #2	Lithic scatter with at least 3 c.s., rock alignment, and a cairn	yes
SBR-8893	P	P-B T/L #2	Trail	yes
SBR-8894	P	P-B T/L #2	Lithic scatter with 3 c.s.	yes
SBR-8895	P	P-B T/L #2	Small lithic scatter	yes

Site	Prehistoric/ Historic	Associated Project Component	Description	Within APE
SBR-8896	P	P-B T/L #2	Single chipping station	yes
SBR-8897	P	P-B T/L #2	Sparse lithic scatter with 4 small c.s.	yes
SBR-8898	P	P-B T/L #2	Trails	yes
SBR-8899	P	P-B T/L #2	Lithic	yes
SBR-8900	P	P-B T/L #2	Lithic scatter	yes
SBR-8901	P	P-B T/L #2	Trail, Lithic scatter, Rock Art	yes
SBR-8902	P	P-B T/L #2	Trail	yes
SBR-8903	P	P-B T/L #2	Trail segment and petroglyphs	yes
SBR-8905	P	P-B T/L #2	Lithics including two c.s.	yes
SBR-8906	P	P-B T/L #2	Trail, lithics, ceramics	yes
SBR-8907	P	P-B T/L #2	Sparse lithic scatter with a pecked rock	yes
SBR-8908	P	P-B T/L #2	Trail with lithics	yes
SBR-8909	P	P-B T/L #2	Trail with lithics	yes
SBR-8910	P	P-B T/L #2	Trail and lithics	yes
SBR-8876/H	P	P-B T/L #2	Trail	yes
SBR-8871/H	P	P-B T/L #2	Trail	yes
SBR-8891/H	P	P-B T/L #2	Lithic scatter with 6 + c.s.	yes
SBR-8904/H	P	P-B T/L #2	Trail, lithics, and glass trade bead	yes
SBR-9853	H	Outside Project Footprint	Atchison, Topeka, & Santa Fe Railway segment with associated trestles and culvers	no
SBR-10521	H	Outside Project Footprint	Colorado River Aqueduct with two dirt access roads on either side of canal	no
SBR-10525	H	Outside Project Footprint	State Route 62 historic road segment with associated water tanks	no
SBR-10526	H	Western periphery inside Project Footprint	Camp Rice	yes

Site	Prehistoric/ Historic	Associated Project Component	Description	Within APE
RIV-8830	H	Outside Project Footprint	Features associated with Camp Rice (rock alignment, rock piles, bottle glass, can scatters)	no
RIV-5982H	H	P-B T/L #2	Historic trash scatter	yes
RIV-5987/H	P/H	P-B T/L #2	Prehistoric trail; Historic WWII training camp	yes
RIV-5988H	H	P-B T/L #2	Historic WWII training camp with rock rings	yes
RIV-5989H	H	P-B T/L #2	Historic WWII training camp with one feature	yes
RIV-5990H	H	P-B T/L #2	Historic WWII dump	yes
RIV-5983H	H	P-B T/L #2	Historic miners camp with tent pads, structures, privy	yes
RIV-5986H	H	P-B T/L #2	Historic miners camp with tent pad cans, lumber, bottles	yes
SBR-4370H	H	P-B T/L #2	Historic road	yes
SBR-8005H	H	P-B T/L #2	Remains of Historic structure (Vidal Substation- 1933)	yes
SBR-8006H	H	P-B T/L #2	Historic dump	yes
SBR-8868H	H	P-B T/L #2	Historic can dump	yes
SBR-8869H	H	P-B T/L #2	Historic can dump	yes
SBR-8870H	H	P-B T/L #2	Historic can dump	yes

* c.s.- chipping station; P-B T/L- Parker Dam-Blyth Transmission Line

**Cultural Resources Table 5
Newly Discovered Historic Features within the
Rice Army Air Field/Camp Rice Facility Footprint**

SITE: RICE ARMY AIR FIELD					
No.	Type	Description	Date	Associations	Other
F001	Well Features	Well casing, abutment (6'x12'), excavated area and backdirt pile. Modern Cans, glass, steel cable, bands, and lumber.	Unknown	None	Surficial
F002	Aerial Marker	Large stone cross (x) aerial marker? Measures 12 m across, made from single course of locally obtained basalt rocks. NE end has an arrow point. Cross is oriented NE/SW and NW/SE. Single hinged lid tobacco tin (Prince Albert) in area.	Post-1950s	None	Surficial
F003	Rock Pile	Small rock pile – baseball sized rocks, a broken Coke bottle, measures 60 cm x 210 cm	1942-1944	Similar to rock pile features F4, F5, and F6, roughly 125-feet east	Surficial
F004	Rock Pile	Teardrop shaped rock pile of baseball sized rocks, 2 m x 3.5 m	Unknown	Similar to rock pile features F3 (125-feet west), F5, and F6 (within 45-feet)	Surficial
F005	Rock Pile	Rock pile, 2.0 m x 1.5 m	Unknown	Similar to rock pile features F3 (125-feet west) F4 (within 45-feet)	Surficial
F006	Rock Pile	Rock pile, 2.5 m x 1.6 m ~40 cm high	Unknown	Similar to rock pile features F3 (125-feet west) F4 (within 45-feet)	Surficial
F007	Rock Pile	2 m x 3 m x 45 cm high of locally available basalt rocks	Unknown	Similar to rock pile features F3, F4, F5, and F6 (700-feet south)	Surficial
F008	Emplacement	Emplacement measuring 12 m x 14 m with earthen embankments about 40 cm high. Opening/entrance to the SE corner. Overall the emplacement is approximately 1 m deep	1942-1944	Parking aprons of the airfield	Low probability of subsurface materials

No.	Type	Description	Date	Associations	Other
F009	Emplacement	Emplacement measuring 8 m x 8 m with earthen berms approximately 30 cm high – entrance to the west. Overall pit is approximately 1 m deep.	1942-1944	Eastern runway	Low probability of subsurface materials
F010	Pit	Small earthen pit measuring 5 x 5 m, approximately 60 cm deep. Inside the pit is a 5 gal. paint bucket, outside is a 1 gal. fuel can and fuel hose	1942-1944	None	Moderate potential of subsurface materials
F011	Rock Pile	2.2 m x 14 m rock feature of basalt rocks, one course deep	Unknown	None	Low potential of subsurface features
F012	Firing Butt	6 m high dirt mound. Has been partially excavated and ATV trails cross over the mound in several spots. The mound is surrounded by modern debris.	Unknown	Taxiways	Low potential of subsurface features
F013	Concrete Slab	Small concrete slab measuring 59" x 59" with four anchor bolts 10" high. Feature is surrounded by a 3 m diameter ring of basalt rocks. This feature is very near the center of the airfield.	1942-1944	None	Low potential of subsurface features
F014	Rock Lined Pit	5 m x 5m rock lined pit, only 30 cm deep. Associated artifacts include an amber glass bottle and a D-cell battery.	1942-1944	None	Moderate potential of subsurface features
F015	Dump Pile	8 m diameter debris dump pile/pit. Pit and banks are filled with burned debris, metal, glass, cans, batteries, fuses, aluminum aircraft parts, hinges, and an antenna.	1942-1944	Runways and the taxiway on west side of field	High potential of subsurface features
F016	Pit	Small pit filled with a 55 gal. drum. Burned debris is around the edges and steel cables and a Coca Cola bottle.	1942-1944	Runways and the taxiway on the west side of field	High potential of subsurface features

No.	Type	Description	Date	Associations	Other
F017	Burned Debris Pit	Pit filled with burned debris including hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", glass jars, misc. metal fragments and modern aluminum cans. Pit measures 1.5 m x 1.5 m and 30 cm deep.	1917-1929; 1964	Two other pits, F-18 and F-19	Low potential of subsurface features
F018	Burned Debris Pit	Pit nearly 1 m deep and 1.5 m x 1.5 m, filled with cans, glass jar and bottle fragments, and a C-cell battery.	1942-1944	Two other pits, F-17 and F-19	Low potential of subsurface features
F019	Burned Debris Pit	Pit measuring 2 m x 1 m, approximately 1 m deep. Filled with burned cans, metal, and glass fragments.	1942-1944	Two other pits, F-17 and F-18	Low potential of subsurface features
F020	Rock Alignment	2.4 m long 60 cm high, and 30 cm wide. Single course of stacked basalt rocks.	Unknown	None	Low potential of subsurface features
F021	Emplacement	10m x 10m emplacement with 60 cm high earthen berms, open to the NE			
F022	Pit	10m x 10m pit with low earthen berms, but pit is 1.25 m deep			
F023	Concrete Slab	10' x 10' concrete slab with 3 1" pipes sticking up out of ground. 10' SE of the slab are fragments of broken concrete and a cut-off 4"x6" post.			
F024	Pit	10 m x 10 m pit with earthen embankments. Near the center of the pit is a 1 m x 1 m pit like a sink hole that is 1 m deep.			
F025	Emplacement	5 m x 5 m emplacement approximately 30 cm deep. Located near the center of the airfield.			

No.	Type	Description	Date	Associations	Other
F026	Burned Debris Pit	2 side by side burn pits. Southern one is 5 m dia x 1 m deep. Northern looks to be filled in. Artifacts include melted glass, burned cans and metal debris, tobacco tins, HIT cans measuring 2 ^{15/16} " x 3 ^{14/16} ", #10 cans, clear glass jars, charcoal, batteries, and misc. metal fragments			
F027	Pit	Square pit 1.5 m x 2 m with straight walls and 2 m deep			
F028	Pit	3 m x 3 m pit, 1 m deep. There is a 1.5 m wide trench dug 6 m to the north, but only 50 cm deep. 2 railroad ties span across the pit with a more recent washing machine base within.			
F029	Pit	Square pit 1.5 m x 1.5 m and 1.5 m deep			
F030	Aerial Marker	Rock alignment 'X' of basalt rocks, 24 m x 24 m, likely to indicate that the runway or taxiway is closed	Post-1950s	None	Surficial
F031	Pit	2 pits with earthen berms. #1 is 5 m x 5 m and #2 is 5 m x 10m. The pits basically share a wall, but pit #2 appears to have entryways to the east and west.			
F032	Pit	2 pits. #1 is 7 m x 7 m and 6 m deep and contains HIT cans and 2 glass jars. Pit #2 is 5 m x 5 m and shares a wall with a basalt rock pile			
F033	Pit	Deep pit, roughly 30 ft deep. Opening measures 1 m x 1.5 m with 4" x 12" beam across the opening			
F034	Barrier	Steel post barrier to block access to the runway. Spaced about every 1'			

No.	Type	Description	Date	Associations	Other
F035	Pit	8m dia pit, very shallow. Contains 15 C and K ration cans, glass jars, and a 1 gal fuel can			
F036	Emplacement	Shallow pit, 50 cm deep, 10 m x 10 m with low embankments			
F037	Trench	Trench ~3 ft deep w/ assoc berm along S			
F038	Berm	Berm ~6-8 ft wide x ~1-2 ft high w/ hollow wood posts 12 x 8 in every ~150-200 ft			
F039	Dirt Mound	Dirt mound with borrow pit, surrounded by can and debris scatter			
F040	Dump	~10 burned trash pits & debris piles with army ration cans and bottles	1942-1944	Road connecting Camp Rice to Rice AAF	Moderate potential of subsurface features
F041	Burned Debris Dump	Burned debris dump 4' area with melted glass fragments			
F042	Emplacement	Square pit, 1 m deep, open to west			
F043	Emplacement	Square pit, 1 m deep, open to west			
F044	Burned Debris Dump	Burned debris 5 m dia area of dumped, burned debris including aqua glass bottle fragments, misc. metal and wood, dump wire, paint cans, chicken wire, metal hanger, oil filter, clear and green glass, nails, and a hinge			
F045	Burned Debris Dump	Charcoal, broom, white ceramic frags, ~30 cans, brn/blu/grn/clr glass frags, &c			
F046	Pit	Pit ~30 ft diameter w/ ~40 cans, grn/brn/clr glass frags			
F047	Burned Debris Dump	~30 cans, grn/brn/clr bottles & frags, wire hanger, &c			
F048	Burned Debris Dump	Berm-bounded pit w/ ~20 cans, grn/brn/clr bottles & frags, wood, &c			

No.	Type	Description	Date	Associations	Other
F049	Well Features	2 well head ~8" diameter and about 25' apart			
F050	Septic Pit	Wood-lined/braced pit 8' x 8' x 15 ft-deep	1942-1944	Concrete apron and east of F-64	Low potential of subsurface features
F051	Concrete Slab	Concrete pad 19'5" x 100' Likely the Airfield Operations Building			
F052	Concrete Slab	Concrete pad 6'5" x 7'7" w/ 8" well			
F053	Concrete Slab	25' x 107'6" foundation w/ brick and diffuse trash Link Trainer Building			
F054	Concrete Slab	10'3" x 31'10" concrete foundation w/ exterior walls 2.5' high and series of 7" x 8" concrete footings for the Dispensary			
F055	Concrete Slab	Concrete structure foundation 20' x 17'10"			
F056	Concrete Slabs	Array of 33 concrete footings, 11" x 11" x 8" high, 3 columns of 11 rows of Officer's Quarters			
F057	Rock Alignment	Rock alignments			
F058	Sidewalk	Concrete sidewalk			
F059	Charcoal Dump	Charcoal mounds			
F060	Concrete Slab	Concrete foundation (machinery?) 8' x 15'10"	1942-1944	Charcoal dump, F-59	Low potential of subsurface features
F061	Wood Posts	Lumber 6"x6" square footings in grid array, 9'7" post-post			
F062	Rock Lined Pit	Rock-lined pit ~1 ft deep			
F063	Concrete Slab	Concrete foundation ~ ground level 20' x 30' and 2' x 4' wood lined pit Kitchen			
F064	Concrete Slab	Concrete foundation ~ ground-level >1ft-high 100' x 60' Headquarters			
F065	Rock Lined Pit	Rock-lined pit ~1 ft deep			
F066	Rock Lined Pit	Rock-lined pit ~1 ft deep			

No.	Type	Description	Date	Associations	Other
F067	Rock Lined Pit	Rock-lined pit ~1 ft deep			
F068	Concrete Slab	Concrete foundation -ground level 20' x 80' Enlisted Mess			
F069	Wood Lined Pit	Wood 2 x 4 box -ground level			
F070	Concrete Slab	Concrete foundation ~ ground level > 1ft high 20' x 60'3"	1942-1944	"Loop Road"	Surficial
F071	Concrete Slab	Concrete footing 3'6" x 3' to support a tower			
F072	Concrete Slab	Concrete foundation ~ ground level> 1 ft high -partially intact 18' x 36'3"			
F073	Concrete Slab	Concrete foundation ~ ground level> 2ft high 20' x 52'3"			
F074	Concrete Slab	Concrete foundation ~ ground level 20' x 30'			
F075	Rock Lined Pit	Rock-lined pit ~0.5 ft deep			
F076	Rock Lined Pit	Rock-lined pit ~1 ft deep			
F077	Rock Lined Pit	3 ea rock-lined pits ~1 ft deep			
F078	Concrete Slab	Concrete foundation ~ ground level > '1 ft high 20'2" x 52'8" Bath House			
F079	Rock Lined Pit	Rock-lined pit ~3 ft deep			
F080	Rock Lined Pit	Rock-lined pit ~1 ft deep w/ cans, barrel, brn/grn bottle glass frags	1942-1944	None	High potential of subsurface features
F081	Rock Lined Trench	Rock-lined trench w/ 2 ft high berm in parallel immediately N			
F082	Burned Debris Dump	Berm-encircled pit ~3 ft deep w/ charcoal, brn glass bottles/frags			
F083	Rock Lined Pit	Rock-lined pit filled to ground level			
F084	Wood Lined Pit	Wood-lined (N end only) pit ~2 ft deep			
F085	Rock Lined Pit	Wood-bordered rock-lined pit ~2 ft deep			
F086	Rock Lined Pit	Rock-lined pit ~1 ft deep			
F087	Concrete Slab	Concrete foundation -ground level 20' x 30'5" and wood lined 2' x 4' pit Kitchen			

No.	Type	Description	Date	Associations	Other
F088	Pit	Circular pit 4' diameter w/ wood posts			
F089	Rock Lined Pit	Rock-lined pit w/ 2" diameter 3' high pipe at center			
F090	Rock-Lined Trench	Rock-lined trench	1942-1944	F-92	Low potential of subsurface features
F091	Rock Lined Pit	2 ea rock-lined pits ~1 ft deep			
F092	Concrete Slab	Concrete foundation ~ground level > 1 ft high 20' x 30' Kitchen			
F093	Wood Lined Trench	Wood-lined trench 4' x 9'5"			
F094	Rock Alignment	Rock alignments			
F095	Concrete Slab	Concrete foundation ~ ground level > 2 ft high 20' x 40'3" Generator			
F096	Trench	Shallow trench w/ 2" x 4" x 2' high posts every 60'			
F097	Burned Debris Pit	Circular pit '6 diameter w/ ~10 cans and burned metal debris			
F098	Burned Debris Pit	Rock-encircled circular pit ~10' diameter w/ - so cans, brn/clr glass frags, &c			
F099	Sign Base	2 long concrete mounds w/ longitudinal slot			
F100	Sign Base	2 ea -2 long concrete mounds w/ longitudinal slot	1942-1944	None	Low potential of subsurface features
F101	Concrete Slab	Concrete foundation -ground level > 1 ft high 28'4" x 20'4" Possible Bath House			
F102	Rock Lined Pit	Rock-lined pit -filled to ground level			
F103	Concrete Slab	Concrete foundation ~ ground level 20' x 30' Possible Kitchen			
F104	Concrete Slab	Concrete foundation ~ ground level 20' x 30'			
F105	Pit	Wood-lined rectangular pit 4' x 5'			

No.	Type	Description	Date	Associations	Other
F106	Rock Lined Pit	4' x 9' rock lined pit within a partially buried wooden frame			
F107	Pit	2 ea rock-lined circular pits 5' diameter, 15' apart E-W			
F108	Pit	Lumber-lined square pit 5' x 5' x 6' deep			
F109	Concrete Slab	Concrete foundation ~ground level 20' x 28'3" Possible Kitchen			
F110	Rock Lined Pit	Rock-lined pit -filled to ground level	1942-1944	F-113	Low-Moderate potential of subsurface features
F111	Pit	Wood-lined rectangular pit ~4 ft deep			
F112	Emplacement	Berm-encircled pit I artillery emplacement -20' diameter entrance to west			
F113	Berm	Berm on eastern end of area, connected to, or drains from F-123			
F114	Burned Debris Pit	Pit ~30' x 20' w/ charcoal, cans, brn/grn/clr glass frags			
F115	Trench	Trench ~2 ft deep			
F116	Rock Lined Pit	Rock-lined pit			
F117	Concrete Slab	Concrete foundation ~ ground level 20' x 28'4" and wood lined pit 2' x 2' Bath House			
F118	Concrete Slab	Concrete foundation ~ ground level 20' x 28'4" and wood lined pit 2' x 2' Lavatory			
F119	Charcoal Dump	Charcoal mounds ~1 ft high			
F120	Rock Alignment	Rock alignments (rocks on lines of polygon)	1942-1944	F-117	Low potential of subsurface features
F121	Pit	Pit 2' x 4' x 2' deep with signs of modern disturbance			

No.	Type	Description	Date	Associations	Other
F122	Rock Lined Pit	Rock-lined pit			
F123	Concrete Slab	Concrete foundation ~ ground level 5' x 7' Kitchen			
F124	Concrete Slab	Concrete foundation ~ ground level 20' x 30'			
F125	Berm	Berm on western end of area, view from aerial near end of runway			
F126	Drain	46" c 77" concrete drain with cast grate measuring 33" x 65" at the intersection of the two runways			
F127	Posts	Line of 6" x 6" poles 58" apart (cut up at 45 deg angle from ground level)			
F128	Berm	Berm on eastern end of runway			
SITE: CAMP RICE					
No.	Type	Description	Date	Associations	Other
F1	Capped Well	Capped well			
F2	Rock Lined Pit	2-meter-diameter basalt rock lined pit with basalt rocks extending out 6 meters in diameter. Associated with the pit are 2 hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", with another small can scatter 6 meters to the SE with more hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", 8 #10 cans, and two 5 gal. paint buckets			
F3	Pit	Rectangular pit, much like a bulldozer cut. 30 meters long x 5 meters wide. Nearby is an associated debris scatter of cans and glass			
F4	Pit	Small pit measuring 1 m x .5 m and 20 cm deep with 1 HIT can, 2 clear glass bottles, 3 clear glass jars, and 1 amber glass bottle			

No.	Type	Description	Date	Associations	Other
F5	Pit	Small square sided pit measuring 25 cm x 50 cm and 20 cm deep, 2 clear glass bottles outside			
F6	Pit	Square pit measuring 2 m x 1.5 m and 40 cm deep. Backdirt piles have burned can fragments and clear, amber and aqua glass fragments. This pit looks like a looter pit.			
F7	Pit	2 m x 2 m pit with charcoal, complete amber and clear glass bottles, Coca Cola bottles, mason jars, can fragments, milk bottles			
F8	Pit	2 m x 2 m pit, 30 cm deep surrounded by low banks with charcoal, can fragments, glass, complete bottles, metal fragments, complete jars, clear ketchup bottles, and amber beverage bottles.			
F9	Emplacement	Semicircular berm ~30 ft diameter with 50 cm high berm w/ -200 army ration cans inside			
F10	Debris Scatter	~40 cans, brn glass bottle, wood 2" x 4" x 5' in -10 ft diameter area			
F11	Pit	Pit ~20 ft diameter w/ -200 cans, clr glass bottle, wire			
F12	Burned Debris Dump	Charcoal, yellow ceramic plate frag, ~20 cans			
F13	Dump	11 20 ft diameter berm-bounded pits, 4 at SW end w/ cans, grn/brn/clr bottles & frags, wood, & c			

**Cultural Resources Table 6
Newly Discovered Historic Artifact Concentrations within the
Rice Army Air Field/Camp Rice Facility Footprint**

SITE: RICE ARMY AIR FIELD					
No.	Type	Description	Date	Associations	Other
C1	Debris Scatter	25+ cans, glass, and metal strapping	1942-1944	None	Surficial
C2	Debris Scatter	30+ cans including key opened meat and fish cans, C-ration cans, glass, and metal strapping			
C3	Debris Scatter	10 five-gal. fuel cans, 1 gal. fuel cans, nails, metal strapping, 3 ring binder, glass fragments, jars, wood, paint cans, D cell batteries, modern cans and debris			
C4	Debris Scatter	40-1 gal. fuel cans, 1 qt. paint cans, 1 pint paint cans, nails, meat cans, cable, binder fragments, 2 x 4 post near middle of scatter			
C5	Debris Scatter	Single-episode dump of fuel cans, melted glass fragments, misc. metal debris, wood, D-cell batteries			
C6	Can Scatter Small	Scatter of 9 cans, 1 hole-in-top can measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", the rest are sanitary type cans			
C7	Burned Debris Dump	Burned trash pile with glass fragments, batteries, can fragments, misc. metal fragments, sheet metal, and wood fragments			
C8	Burned Debris Dump	Burned trash pile with 20+ cans, can fragments, clear glass fragments within a 3 meter diameter area			
C9	Debris Scatter	Rolls of 1/8" hardware cloth and metal poles with a 'T' joint in middle			

No.	Type	Description	Date	Associations	Other
C10	Can Scatter	Small can scatter of 8 cans within a 3 meter area. Cans include hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", #10 cans, and sanitary cans.			
C11	Debris Scatter	5 meter diameter pit filled with mixed historic and modern debris. Historic items include 5 gal. fuel cans, #10 cans, coffee cans, stove pipe, galvanized metal bucket, 55 gal drum, ammo box lid, ceramic insulator, clear glass fragments, steel cable. Modern debris includes aluminum topped beverage cans. The nature of this debris appears that it was collected from the area and dumped in this pit	1942-1944	Western runway	Surficial
C12	Can Scatter	Small fuel and paint can scatter with 15 cans in a 2 meter area			
C13	Debris Scatter	3 m. diameter debris dump with metal straps, 1 gal fuel cans, aluminum fragments, rubber hose, brackets, galvanized steel pipe, and 5 gal can lids			
C14	Debris Scatter	Small scatter over 5 meter area containing metal wire spool, pipe, paint cans and lids, paint, 1 gal can, misc. metal fragments			
C15	Burned Debris Dump	3 m x 20 m burned debris dump with #10 cans, paint cans, stove pipe, C-rationcans, 5 gal. fuel, amber bottles, wire, food/fruit cans, and hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ "			
C16	Debris Scatter	Debris scatter containing tobacco tins, hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", clear, green, and amber glass fragments, pink ceramic toilet paper holder, Coca Cola bottle, and wire			

No.	Type	Description	Date	Associations	Other
C17	Debris Scatter	Small scatter within a 1.5 meter area. 12 cans including sardine, beverage, and food/fruit cans, also clear glass bottle finish and an amber bottle fragment			
C18	Debris Scatter	21 cans including a brake fluid can, #10 cans, C-ration cans, 1 pint sized paint can, wooden frame, 3 clear glass jars, 2 clear glass bottles			
C19	Can Scatter	16 cans in a 2 m area, C-ration cans			
C20	Can	3 cans in a 1 m area, all C cans			
C21	Can Scatter	20 cans in a 6m area, all Army ration	1942-1944	None	Surficial
C22	Debris Scatter	Approximately 400 cans including Army ration cans, HIT cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", paint cans, 1 gal paint cans, tobacco tins, burned/melted clear, amber and green glass, nails, metal strapping, and rubber hose in a 10 m area			
C23	Debris Scatter	Debris dump in a 15m x 10m area. Contains army ration cans, glass fragments, a padlock, yellow ceramic plate fragments, batteries, metal strapping, cable, light bulb base.			
C24	Burned Debris	100 cans in a 4 m area. All Army ration cans, HIT cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", 1 gal fuel, dump batteries, clear glass fragments, ketchup bottles, wire, and metal strapping			
C25	Burned Debris Dump	Burned debris dump with mostly melted and fragmented glass, a few can fragments, batteries, hose clamp, first aid tape reel, and charcoal in a 7 m area			
C26	Burned Debris Dump	Army ration cans, HIT cans, 1.5 meter charcoal dump, nails, Wire, cable, and glass sparsely scattered over a 12 meter area			

No.	Type	Description	Date	Associations	Other
C27	Can Scatter	50 Army ration cans, #10, C-ration, HIT, in a 3 m x 2 m area			
C28	Can Scatter	100+ flattened food cans			
C29	Debris Scatter	200+ army ration food cans (~50 flattened), c1r glass bottle frags, &c in ~10 ft diameter area			
C30	Debris Scatter	~50 cans, clr glass frags, &c			
C31	Can Scatter Area	~3 ft diameter w/ ~20 cans	1942-1944	None	Surficial
C32	Dump	Metal box beam & ducting, cans, charcoal, brn glass frags, &c			
C33	Debris Scatter Area	~4 ft diameter – ~20 cans + area 4 ft diam 10m N -brn/grn/clr glass + 10m S 2 ft diameter 7 cans			
C34	Can Scatter Area	~4 ft diameter w/ ~20 cans			
C35	Debris Scatter	Yellow ceramic plate frags, 100+ cans, metal pipe, wire, wood, &c			
C36	Can Scatter	Triangular area w/ concentration of ~20-30 cans at each corner			
C37	Can Scatter Area	-8 ft diameter --40 cans, automotive leaf-spring piece			
C38	Construction Debris	Area ~30'x20' w/ lumber, ~10 cans, wire mesh			
C39	Construction Debris	Area ~30'x20' w/ lumber, plumbing, plaster, wire mesh			

SITE: CAMP RICE

SITE: CAMP RICE					
C01	Can Scatter	40+ Hole-in-Top cans measuring 2 ¹⁵ / ₁₆ x 3 ¹⁴ / ₁₆ and metal strapping			
C02	Debris Scatter	60+ cans including #10 and hole-in-top cans measuring 2 ¹⁵ / ₁₆ x 3 ¹⁴ / ₁₆ , clear glass ketchup bottles and quart jars			
C03	Debris Scatter	40+ cans, sanitary type, square/rectangle meat cans with key opening, C-ration cans within a 1 meter square area			
C04	Debris Scatter	29 cans within a 1 meter area, all the same, round with key opened C-ration cans			
C05	Can Scatter	15 cans, 3 #10, sanitary type, HIT 2 ¹⁵ / ₁₆ x 3 ¹⁴ / ₁₆			
C06	Debris Scatter	7 -#10 cans, 60 food/milk cans -sanitary type and HIT 2 ¹⁵ / ₁₆ x 3 ¹⁴ / ₁₆ , 1 glass mason jar, wire			
C07	Debris Scatter	1/8" hardware cloth in rolls, D-cell batteries, 1 gal. fuel can, 5 gal fuel can, metal fragments, and 1" diameter pipe.			
C08	Debris Scatter	50+ cans, hole-in-top cans measuring 2 ¹⁵ / ₁₆ x ¹⁴ / ₁₅ and 2 ⁸ / ₁₆ x 2 ⁶ / ₁₆ , broken mason jar, coffee can, and 1 qt paint cans			
C09	Debris Scatter	100+ cans including 1 qt. paint cans, oil filter, hole-in-top cans measuring 2 ¹⁵ / ₁₆ x 3 ¹⁴ / ₁₆ ", battery fragments, and glass fragments			
C10	Debris Scatter	60+ cans including hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", quart glass jars, 1 qt paint cans, dimensional lumber, and #10 cans .			
C11	Can Scatter	20 cans, 2-#10 cans, 18 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ " with "Punch Here" embossed on lid.			

No.	Type	Description	Date	Associations	Other
C12	Debris Scatter	Rolls of 1/8" hardware cloth, hole-in-top can measuring 2 ^{15/16} x 3 ^{14/16} , C-ration cans, metal strapping, fuel can lid, D-cell battery			
C13	Can Scatter	2 discrete dumps of ~50 cans each, only 3 meters apart, each dump is 1.5 meter in diameter. Each contains hole-in-top cans measuring 2 ^{15/16} x 3 ^{14/16} ", sanitary type cans, meat cans with key opening, metal strapping, C-ration cans			
C14	Debris Scatter	Small scatter of 20+ cans, most crushed, a bottle finish and glass fragments			
C15	Debris Scatter	16 #10 cans, 4 hole-in-top cans measuring 2 ^{15/16} x 3 ^{14/15} , 1 hole-in-top can measuring 2 ^{8/16} x 2 ^{6/16} ", and glass fragments			
C16	Debris Scatter	5 hole-in-top cans measuring 2 ^{15/16} x 3 ^{14/16} ", 5 #10 cans, 2 quart sized juice cans, 2 large meat cans, and at least 6 fragmented jars			
C17	Debris Scatter	80+ cans with another 80 extending down the wash, nails, batteries, misc. metal fragments, wire, drywall material, glass jars			
C18	Can Scatter	40+ cans, most fruit cans, 3 hole-in-top cans measuring 2 ^{15/16} x 3 ^{14/16} ", large square "Roast Beef" can with ingredients embossed			
C19	Debris Scatter	Large dump with a 5 gal. fuel can, 1 5 gal paint bucket, 25 1 gal. fuel cans, 6 1 gal paint cans, 30+ fruit cans, hole-in-top cans measuring 2 ^{5/16} x 3 ^{14/16} ", several #10 cans, charcoal/ash, batteries, lumber, window and jar glass.			

No.	Type	Description	Date	Associations	Other
C20	Debris Scatter	25+ #10 cans, 20 hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", 16 sanitary type fruit cans, and 2 glass quart jars			
C21	Glass Scatter	Glass debris dump with clear, amber, and green glass fragments, some melted. Also present are Coca Cola bottles and some wire and batteries			
C22	Debris Scatter	6 clear glass 1 quart jars, 2 fragmented jars, and 5 crushed cans			
C23	Can Scatter	6 large "Roast Beef" cans, 5 coffee cans, 3 #10 cans, 15 fruit cans, and 4 hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ "			
C24	Debris Scatter	100+ crushed/flattened cans with recognizable #10 cans, food and fruit cans, hole-in-top cans, glass bottle fragments, and a battery			
C25	Glass Scatter	Scatter of glass bottle fragments within a 1 meter area			
C26	Construction Debris	Construction debris scatter with asbestos pipe, cans, ceramic plate fragments, springs, nails, misc. metal fragments			
C27	Debris Scatter	Glass and can scatter with steel cable, metal strapping, muffler, 3 ring binder, 1 gal paint cans all within a 10 meter diameter area.			
C28	Debris Scatter	Can scatter and glass fragments, hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", an auto gauge			
C29	Debris Scatter	can scatter, bottle caps, misc metal fragments, 1 quart juice cans, oil filter, C-ration meat cans, Coca Cola bottle, clear glass bottles			

No.	Type	Description	Date	Associations	Other
C30	Burned Debris	Burned trash pile, no recognizable cans, but had glass fragments, a canteen holder, misc. metal dump fragments, can lids, wire, small			
C31	Glass Scatter	2 episode glass bottle dump. Mostly clear glass bottles and jars with some amber glass. Most glass is melted. Only 5 cans are present. Scatter within a 2 m x 3 m area			
C32	Burned Debris Dump	Burned bottle and debris dump with clear and amber glass bottles and jars. Other items noted include a fuse, paint cans, misc. metal vehicle parts, metal straps, wire hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ " within a 5 meter diameter area.			
C33	Burned Debris Dump	Burned debris pile including melted glass of clear, amber, and green bottles and clear jars, wire spool, tobacco tin, meat can, shoe heel, and batteries			
C34	Burned Debris Dump	Burned debris pile including melted/burned clear, amber, and green bottle glass, metal clothes hanger, Coca Cola bottle, bottle caps, batteries all within a 1 meter diameter area.			
C35	Debris Scatter	Large debris dump, 5 meters in diameter. 200+ cans and lids, clear glass jars, green glass bottle fragments, 5 gal. fuel can lid, 1 gal. fuel can, #10 cans, hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", food/fruit cans, can lids, .50 cal shell casings, ammunition links for linked .50 cal rounds.			
C36	Debris Scatter	Can scatter of all flattened cans with a few melted bottle fragments. Over 100 cans within a 1 meter diameter area. Cans recognized include meat, fish, and food/fruit cans, bottle caps, and a ketchup bottle.			

No.	Type	Description	Date	Associations	Other
C37	Can Scatter	50 cans including hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", #10 cans, sanitary type food/fruit cans. A few meters away are 3 clear glass jars and fragments and a few more cans.			
C38	Debris Scatter	20 cans including 5 #10 cans, hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", ketchup bottle, and clear glass jar fragments			
C39	Can Scatter	20 cans in one dump, all sanitary type food/fruit cans or #10 cans, with a single clear glass bottle			
C40	Burned Debris	30 cans including hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", sanitary type food/fruit cans, #10 cans, meat/roast beef cans, C-rations, clear glass fragments, metal straps, hacksaw blade, and aluminum scrap -all burned with some charcoal present.			
C41	Can Scatter	16 cans in a 1 meter diameter area including food/fruit cans, #10 cans, hole-in-top cans measuring 2 ¹⁵ / ₁₆ " x 3 ¹⁴ / ₁₆ ", square C-ration can, and one ketchup bottle.			
C42	Debris Scatter	Rolls of 1/8" hardware cloth and metal poles with a 'T' joint in middle and 5 can fragments			
C43	Can Scatter	25 cans in a 4 m area, mostly C-ration cans (fruit, vegetable, and meat) fish cans, 2 clear glass jars, and a metal flask			
C44	Debris Scatter	20 Army ration cans and 2 clear glass bottles in a 2 meter area			
C45	Can Scatter	60 Army ration cans and metal strapping in a 8' area			
C46	Debris Scatter	3 trash concentrations -3 ea wood 2 in x 4 in x 3 ft 4m E, ~10 cans 8m NW, ~30 cans 8m SSE			

No.	Type	Description	Date	Associations	Other
C47	Debris Scatter	250 cans, clr glass jars/frags, banding, plumbing pipe in ~20 ft diameter area			
C48	Debris Scatter	~20 cans, clr glass jar frags, wire in ~20 ft diameter area			
C49	Can Scatter	~20 cans in ~10 ft diameter area			
C50	Burned Debris Dump	~100 cans, clr glass frags in ~10 ft diam w/ ~2 ft diam charcoal 5m NW & brn/grn/clr glass 10m SW			
C51	Can Scatter	~30 cans, clr jar frags & grn bottle frags, wire in ~6 ft diameter area			
C52	Can Scatter	~16 cans in ~6 ft diameter area			
C53	Debris Scatter	Area ~8 ft diameter w/ ~20 cans, brn bottles/frags, banding			
C54	Debris Scatter	Area ~9 ft diameter w/ ~60 cans, clr glass bottles/jars/frags, banding			
C55	Debris Scatter	Area ~12 ft diameter w/ ~60 cans, clr glass bottles/jars/frags, wire, &c			
C56	Burned Debris Dump	Area ~20 ft diameter w/ ~10 cans, borrlcaps, brn/grn/clr glass bottles/frags, banding, wire, &c			
C57	Debris Scatter	Cans and glass			
C58	Debris Scatter	Cans and glass			
C59	Debris Scatter	Cans and glass

HAZARDOUS MATERIALS MANAGEMENT

Testimony of Geoff Lesh, PE and Rick Tyler

SUMMARY OF CONCLUSIONS

The U.S. Bureau of Land Management (BLM), Western Area Power Administration (Western) and Energy Commission staff (staff), hereafter jointly referred to as agencies, have reviewed the Rice Solar Energy Project (RSEP or proposed project) in accordance with the requirements of the National Environmental Policy Act (NEPA) and the California Environmental Quality Act (CEQA). With respect to CEQA, staff concludes that hazardous materials use at the proposed RSEP would not present a significant impact on the public or environment. With adoption of the proposed mitigation measures/conditions of certification, the proposed project would comply with all applicable laws, ordinances, regulations, and standards (LORS).

These Conditions of Certification meet the Energy Commission's responsibility to comply with the California Environmental Quality Act and serve as staff's recommendations for the Energy Commission to consider in its decision to avoid or reduce the severity of hazardous material-related impacts to less than significant and for the project to conform to all applicable LORS. The identification of relevant and reasonable mitigation measures also conforms to National Environmental Policy Act (NEPA) requirements for BLM's and Western's analysis that can be considered in their Records of Decision.

INTRODUCTION

The purpose of this **Hazardous Materials Management** section of this Preliminary Staff Assessment/Draft Environmental Impact Statement (PSA/DEIS) is to determine if the proposed RSEP could potentially cause significant impacts on the public from the use, handling, storage, or transportation of hazardous materials at the proposed project site. If significant adverse impacts on the public are identified, Energy Commission staff must evaluate facility design alternatives and additional mitigation measures to reduce those impacts to the extent feasible.

This analysis does not address the potential exposure of workers to hazardous materials used at the proposed project site. Employers must inform employees of hazards associated with their work and provide those employees with special protective equipment and training to reduce the potential for health impacts from the handling of hazardous materials. The **Worker Safety and Fire Protection** section of this document describes the protection of workers from those risks.

For this analysis, staff examines plausible potential loss of containment incidents (spills) for the hazardous materials to be used at the proposed facility. The worst case plausible event, regardless of cause, is considered, and analyzed to see whether the risk to local populations is significant. Hazardous material handling and usage procedures are designed to reduce the likelihood of a spill, to reduce its potential size, and to prevent or reduce the potential migration of a spill off site to the extent that there won't be significant off-site impacts. These measures look at potential direct contact from runoff

of spills, air-borne plume concentrations, and the potential for spills to mix with runoff water and be carried offsite. Generally, staff seeks to confirm that the applicant has proposed secondary containment basins for containing hazardous material liquids, and that volatile chemicals would have a restricted exposure to the atmosphere after capture. Containment basins are designed to be able to hold the contents of a full tank plus the potential rainfall from a 25-year storm without any loss of containment. In the event of a spill, the spilled material, along with any mixed-in water and any contaminated soils, would then be placed into containers and processed and disposed of as required by regulations.

Hazardous materials such as mineral and lubricating oils, corrosion inhibitors, herbicides, and acids and bases to control pH would be present at the proposed project site. Hazardous materials used during the construction phase include gasoline, diesel fuel, motor oil, lubricants, and small amounts of solvents and paint. No acutely toxic hazardous materials would be used on-site during construction. None of these materials pose a significant potential for off-site impacts as a result of the quantities on-site, their relative toxicity, their physical states, and/or their environmental mobility.

Although no natural gas is stored or used, the project would involve the temporary handling of moderate amounts of liquid petroleum gas (LPG, or propane) during the start-up commissioning phase. Propane poses some risk of both fire and explosion. The risk of a fire and/or explosion on-site can be reduced to insignificant levels through adherence to applicable codes and the development and implementation of effective safety management practices.

The RSEP would also require the transportation of certain liquid and solid hazardous materials to the facility. This document addresses all potential impacts associated with the use, storage, and transport of hazardous materials.

LAWS, ORDINANCES, REGULATION, AND STANDARDS

The following federal, state, and local laws and policies apply to the protection of public health and hazardous materials management. Staff's analysis examines the project's compliance with these requirements.

**HAZARDOUS MATERIALS MANAGEMENT Table 1
Laws, Ordinances, Regulations, and Standards (LORS)**

Applicable Law	Description
Federal	
The Superfund Amendments and Reauthorization Act of 1986 (42 USC §9601 et seq.)	Contains the Emergency Planning and Community Right To Know Act (also known as SARA Title III).
The Clean Air Act (CAA) of 1990 (42	Establishes a nationwide emergency planning and response program, and imposes reporting requirements for businesses that

USC 7401 et seq. as amended)	store, handle, or produce significant quantities of extremely hazardous materials.
The CAA Section on Risk Management Plans (42 USC §112(r)	Requires states to implement a comprehensive system to inform local agencies and the public when a significant quantity of such materials is stored or handled at a facility. The requirements of both SARA Title III and the CAA are reflected in the California Health and Safety Code, section 25531, et seq.
49 CFR 172.800	Requires that the suppliers of hazardous materials prepare and implement security plans in accordance with U.S. Department of Transportation (DOT) regulations.
49 CFR Part 1572, Subparts A and B	Requires that suppliers of hazardous materials ensure that their hazardous material drivers comply with personnel background security checks.
The Clean Water Act (CWA) (40 CFR 112)	Aims to prevent the discharge or threat of discharge of oil into navigable waters or adjoining shorelines. Requires a written spill prevention, control, and countermeasures (SPCC) plan to be prepared for facilities that store oil that could leak into navigable waters.
6 CFR Part 27	The CFATS (Chemical Facility Anti-Terrorism Standard) regulation of the U.S. Department of Homeland Security (DHS) that requires facilities that use or store certain hazardous materials to submit information to the DHS so that a vulnerability assessment can be conducted to determine what certain specified security measures shall be implemented.
State	
California Health and Safety Code, section 25531 to 25543.4	The California Accidental Release Program (Cal-ARP) requires the preparation of a Risk Management Plan (RMP) and Off-site Consequence Analysis (OCA) and submittal to the local Certified Unified Program Authority (CUPA) for approval.
Title 8, California Code of Regulations, Section 5189	Requires facility owners to develop and implement effective safety management plans to ensure that large quantities of hazardous materials are handled safely. While these requirements primarily provide for the protection of workers, they also indirectly improve public safety and are coordinated with the RMP process.
Title 8, California Code of Regulations, Section 5189	Sets forth requirements for design, construction, and operation of the vessels and equipment used to store and transfer ammonia. These sections generally codify the requirements of several industry codes including the American Society for Material Engineering (ASME) Pressure Vessel Code, the American National Standards Institute (ANSI) K61.1, and the National Boiler and Pressure Vessel Inspection Code. These codes apply to anhydrous ammonia but are also used to design storage facilities for aqueous ammonia.
Process Safety	Requires facility owners to develop and implement effective process

Management: Title 8 CCR Section 5189	safety management plans when toxic, reactive, flammable, or explosive chemicals are maintained on site in quantities that exceed regulatory thresholds.
California Health and Safety Code, Sections 13240 – 13243.6	California Propane Storage and Handling Safety Act adopts regulations setting for safety standards for siting and construction of fixed propane storage systems, fire safety compliance requirements, and training requirements
California Health and Safety Code, Section 41700	Requires that “No person shall discharge from any source whatsoever such quantities of air contaminants or other material which causes injury, detriment, nuisance, or annoyance to any considerable number of persons or to the public, or which endanger the comfort, repose, health, or safety of any such persons or the public, or which cause, or have a natural tendency to cause injury or damage to business or property.”
California Safe Drinking Water and Toxic Enforcement Act (Proposition 65)	Prevents certain chemicals that cause cancer and reproductive toxicity from being discharged into sources of drinking water.
LOCAL	
Riverside County Fire Code, Riverside County Code Chapter 8.32: Ordinance No. 787	Adopts the California Fire Code, 2007 Edition, with some of its appendices, into Riverside County regulations.
Disclosure of Hazardous Materials and the Formulation of Business Emergency Plans: Riverside County Ordinance 651	Requires disclosure where businesses handle hazardous materials and requires the development of response plans; designates Riverside County Department of Environmental Health as responsible for administration and enforcement of local codes.

The Certified Unified Program Agency (CUPA) with the responsibility to review the Hazardous Materials Business Plan (HMBP) is the Riverside County Environmental Health Department (RCEHD). With regard to seismic safety issues, the site is located in a seismically active region of California. Construction and design of buildings and vessels storing hazardous materials will meet the appropriate seismic requirements of the 2007 California Building Code (RSEP 2009a, Section 2.3.1.1.1).

METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

Staff reviewed and assessed the potential for the transportation, handling, and use of hazardous materials to impact the surrounding community. All chemicals and natural gas were evaluated. Staff's analysis examines the potential impacts on all members of the population including the young, the elderly, and people with existing medical conditions that may make them more sensitive to the adverse effects of hazardous materials. In order to accomplish this goal, staff utilizes the most current acceptable public health exposure levels (both acute and chronic) to protect the public from the effects of an accidental chemical release.

In order to assess the potential of released hazardous materials traveling off-site and affecting the public, staff analyzed several aspects of the proposed use of materials at the facility. Staff recognizes that some hazardous materials must be used at power plants. Therefore, staff conducted its analysis by focusing on the choice and amount of chemicals to be used, the manner in which the applicant would use the chemicals, the manner by which it would be transported to the facility and transferred to facility storage tanks, and the way in which the applicant plans to store those materials on-site.

Staff reviewed the applicant's proposed engineering and administrative controls for hazardous material use. Engineering controls are physical or mechanical systems such as storage tanks or automatic shut-off valves that can prevent a spill of hazardous material from occurring, or that can limit the spill to a small amount or confine it to a small area. Administrative controls are rules and procedures that workers must follow to help either prevent accidents or keep them small if they do occur. Both engineering and administrative controls can act as either methods of prevention or methods of response and minimization. In both cases, the goal is to prevent a spill from moving off-site and harming the public.

Staff reviewed and evaluated the proposed use of hazardous materials, as described by the applicant (RSEP2009a, section 5.5 and CH2MHill 2010v). Staff's assessment followed the five steps listed below:

- Step 1: Staff reviewed the chemicals and amounts proposed for on-site use, as listed in Tables 5.5-1, 5.5-2, and 5.5.3 of the Application for Certification (AFC) (RSEP2009a) and SII1-1 (CH2MHill 2010v), and determined the need and appropriateness of their use. Only those that are needed and appropriate are allowed to be used. If staff feels that a safer alternative chemical can be used, staff would recommend or require its use, depending upon the impacts posed.
- Step 2: Those chemicals, proposed for use in small amounts or whose physical state is such that there is virtually no chance that a spill would migrate off the site and impact the public, were removed from further assessment.
- Step 3: Measures proposed by the applicant to prevent spills were reviewed and evaluated. These included engineering controls such as automatic shut-off valves and different size transfer-hose couplings and administrative controls such as worker training and safety management programs.
- Step 4: Measures proposed by the applicant to respond to accidents were reviewed

and evaluated. These measures also included engineering controls such as catchment basins and methods to keep vapors from spreading, and administrative controls such as training emergency response crews.

- Step 5: Staff analyzed the theoretical impacts on the public of a worst-case spill of hazardous materials even with the mitigation measures proposed by the applicant. When mitigation methods proposed by the applicant are sufficient, no further mitigation is recommended. If the proposed mitigation is not sufficient to reduce the potential for adverse impacts to an insignificant level, staff would propose additional prevention and response controls until the potential for causing harm to the public is reduced to an insignificant level. It is only at this point that staff can recommend that the project be allowed to use hazardous materials.

PROPOSED PROJECT

SETTING AND EXISTING CONDITIONS

The RSEP is within a larger, privately owned holding that is 3,324 acres. Within the project parcel will be the administration buildings area, heliostat field with power block, and evaporation pond areas, (collectively, the project site or facility site) totaling 1,410 acres, that will be surrounded by a security fence. Areas outside the facility site but within the project parcel will not be fenced or developed or disturbed as part of the RSEP. The site is primarily on previously disturbed private land (RSEP 2009a, AFC pg. ES-4). Existing use adjacent to the proposed project site consists of undeveloped open space uses to the east, south, and west. Along the northern boundary of the site, State Route 62, the California Aqueduct, and the Arizona-California Railroad run parallel to the site (RSEP 2009a, AFC Section 5.7.2.1).

Several characteristics of an area in which a project is located affect its potential for an accidental release of a hazardous material. These include:

- local meteorology;
- terrain characteristics; and
- location of population centers and sensitive receptors relative to the project.

METEOROLOGICAL CONDITIONS

Meteorological conditions, including wind speed, wind direction, and air temperature, affect both the extent to which accidentally released hazardous materials would be dispersed into the air and the direction in which they would be transported. This affects the potential magnitude and extent of public exposure to such materials, as well as their health risks. When wind speeds are low and the atmosphere is stable, dispersion is severely reduced and can lead to increased localized public exposure.

Recorded wind speeds and ambient air temperatures are described in the Air Quality section (5.1) and Appendix 5.1C of the Application for Certification (AFC) (RSEP2009a).

TERRAIN CHARACTERISTICS

The RSEP will be located in rural eastern Riverside County, California. The project site

is along State Route (SR) 62 between Parker, Arizona, and Twentynine Palms, California. The project will be located on private land that was used during World War II as the site of the Rice Army Airfield, an airfield used to train infantry air support between 1942 and 1944, before being converted to a private airfield for a short time during the 1950s, and then abandoned. The project is located in a sparsely settled portion of the Sonoran Desert. The nearest residences are located in Vidal Junction, about 15 miles northeast of the site; and at the Metropolitan Water District's Iron Mountain Pumping Plant, about 17 miles to the west. The nearest town offering services is Parker, Arizona, approximately 32 miles east by road. Blythe, California is approximately 40 miles south by road. Twentynine Palms, California is 75 miles west (RSEP 2009a, Section 5.12.1).

LOCATION OF EXPOSED POPULATIONS AND SENSITIVE RECEPTORS

The general population includes many sensitive subgroups that may be at greater risk from exposure to emitted pollutants. These sensitive subgroups include the very young, the elderly, and those with existing illnesses. In addition, the location of the population in the area surrounding a project site may have a large bearing on health risk.

There are no sensitive receptors such as schools, day care facilities, residences, or hospitals within six miles of the project site. The nearest school to the project site is La Pera Elementary School at 19121 Tahbo Road, Parker, Arizona, approximately 24 miles east-southeast of the project site. The nearest hospital is La Paz Regional Hospital at 1200 W. Mohave Road, Parker, Arizona, which is approximately 30 miles to the east-northeast. The nearest residential receptor is in Vidal Junction, about 15 miles northeast. The nearest town is Parker, Arizona (population 3,181), approximately 32 miles east. A residential settlement is located at the Metropolitan Water District of Southern California's Iron Mountain Pumping Plant, approximately 17 miles west (RSEP2009a, sections 5.5.1 and 5.9.1, figure 5.5-1).

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

DIRECT/INDIRECT IMPACTS AND MITIGATION

Proposed Project

Small Quantity Hazardous Materials

In conducting this analysis, staff determined in Steps 1 and 2 that most of the proposed materials, although present at the proposed facility, pose a minimal potential for off-site impacts since they would be stored in either solid form or in small quantities, have low mobility, low vapor pressure, or low levels of toxicity. These hazardous materials, which were eliminated from further consideration, are discussed briefly below.

During the construction phase of the project, the only hazardous materials proposed for use include paint, cleaners, solvents, gasoline, diesel fuel, motor oil, welding gases, and lubricants. Any impact of spills or other releases of these materials would be limited to the site because of the small quantities involved, the infrequent use and hence reduced chances of release, and/or the temporary containment berms used by contractors.

Petroleum hydrocarbon-based motor fuels, mineral oil, lube oil, and diesel fuel all have very low volatility and would represent limited off-site hazards, even in larger quantities.

During operations, hazardous chemicals such as cleaning agents, lube oil, sulfuric acid, sodium hydroxide, diesel fuel and other various chemicals (see **Hazardous Materials Appendix A** for a list of all chemicals proposed to be used and stored at RSEP) would be used and stored on-site and represent limited off-site hazard due to their small quantities, low volatility, and/or low toxicity.

After removing from consideration those chemicals that pose no risk of off-site impact in Steps 1 and 2, staff continued with Steps 3, 4, and 5 to review the remaining hazardous materials: hydrogen, sodium hypochlorite, sulfuric acid, and liquefied petroleum gas.

Large Quantity Hazardous Materials

Aqueous Ammonia

The RSEP facility may utilize aqueous ammonia (19% NH₃) as an option for emissions control of the salt melting and conditioning equipment during plant commissioning activities. The ammonia will be brought onsite by a licensed contractor in tanker trucks. Liquid ammonia tanker trucks have capacities of up to 11,400 gallons. The capacity of the tanker trucks expected to be used for the RSEP is 7,500 gallons. A maximum of two tanker trucks will be onsite at any time; thus, the maximum amount of ammonia onsite at the RSEP will be 15,000 gallons. The trucks will stay onsite until empty and no permanent ammonia storage tanks will be built for the RSEP.

The tanker trucks will be surrounded by a secondary containment structure capable of holding the full contents of the tank and accumulated precipitation. The tanker trucks will only be onsite during plant commissioning. Storage and use of ammonia would be subject to the requirements of the California Fire Code, Article 80, as well as the California Accidental Release Prevention (CalARP) program. Article 80 of the California Fire Code contains specific requirements for control of liquid and gaseous releases of hazardous materials. Secondary containment in the form of a bermed containment area under and surrounding the ammonia tank will be provided for the loading area. The RMP is in accordance with CalARP, which has additional requirements such as specifying safe handling procedures for the ammonia and emergency response procedures in the event of an accidental release. Because sodium hypochlorite and aqueous ammonia are incompatible chemicals, the sodium hypochlorite will be stored in a bermed area for secondary containment (an area capable of capturing any spills) that will be designed such that it is separated from the ammonia, to eliminate potential interactions/reactions in the event that the chemicals are accidentally released.

Because of its hazardous properties, ammonia is classified as a regulated substance, and an accidental release of aqueous ammonia could present a human health hazard. As its name indicates, aqueous ammonia is mixed with water. If the ammonia were to leak or be released without proper controls, the ammonia could escape or evaporate as a gas into the atmosphere. Its vapor is lighter than air and has the same pungent odor as household ammonia. Mixing the ammonia with water makes it less volatile, slows its evaporation, and makes it less likely that concentrations in area will become hazardous, in the event of an accidental release. Pure ammonia (NH₃) is a volatile, acutely

hazardous chemical that is stored under pressure as a liquid and becomes a toxic gas if released. Additionally, ammonia is colorless and flammable. Ammonia gas can be toxic to humans at sufficient concentrations. The odor threshold of ammonia is about five parts per million (ppm), and minor irritation of the nose and throat will occur at 30 to 50 ppm.

The hazard to facility workers will be mitigated by facility safety equipment, hazardous materials training, and emergency response planning (BSEP 2009a, Section 5.16). In a catastrophic accident, toxic ammonia gas could migrate offsite and affect the health of humans at locations surrounding the facility. Facility design will minimize the potential for harm to humans located offsite. The project site is very isolated and about 15 miles from the nearest residence. The site is surrounded by unoccupied, open desert unlikely to be used by members of the public. Furthermore, the RSEP power block, where the ammonia will be used during the liquid salt melting and conditioning process, is approximately one mile from the nearest area with public use, which is SR 62. Staff's experience with modeling of 19% aqueous ammonia indicates that it is highly unlikely that airborne concentrations of ammonia greater than 75 ppm will be reached at the site fence line, even in the worst case accidental release scenario.

Aqueous ammonia consists of ammonia, a colorless, non-flammable liquefied gas, dissolved into water. Under normal storage conditions, ammonia would not evaporate to the atmosphere because it is contained in a sealed tank that maintains the ammonia in a state that precludes evaporation. In the unlikely event that a release were to occur, ammonia could evaporate directly to the atmosphere. Ammonia vapor is combustible only within a narrow range of concentrations in air. It will ignite at a temperature of 1,204°F within vapor concentration limits between 15% and 28% and the presence of a strong ignition source. Outside conditions that would support these vapor concentrations are rare. The evaporation rate of ammonia is similar to water, which is sufficiently low that the lower explosive limit of 15% (or 15,000 ppm) will not be reached. Staff therefore believes that the temporary storage and use of 19% aqueous ammonia at the proposed project poses an insignificant risk to the off-site public.

Hydrogen

Hydrogen would be stored on site as a generator coolant. The amount will be less than the Reportable Quantity as defined in the CalARP regulations, and would be stored in DOT approved "tube trailers" that incorporate safety systems and pressure relief valves. Based upon staff's knowledge about the use of this, an accidental release of hydrogen gas poses an insignificant risk to the off-site public.

Sodium Hydroxide

Sodium hydroxide would be stored on site but would not pose a risk of off-site impacts because it has relatively low vapor pressure and thus spills would be confined to the site. Therefore, no further analysis is needed.

Sodium Hypochlorite

According to the table included in Applicant's Supplemental Information Item 1 - Hazardous Material List (CH2MHill 2010v), 17,000 gallons of sodium hypochlorite would

be stored at the site. Sodium hypochlorite has a low potential to affect the off-site public because its vapor pressure is low and it is in an aqueous solution. In fact, hypochlorite is used at many such facilities as a substitute for chlorine gas, which is much more toxic and much more likely to migrate off-site because it is a gas and is stored in concentrated form under pressure. Thus, the use of a water solution of sodium hypochlorite is much safer to use than the alternative chlorine gas. The amount of sodium hypochlorite that would be stored on the site is below the Reportable Quantity as defined in the Cal-ARP regulations. Based upon staff's knowledge about the use of this material and the modeling of accidental releases, an aqueous solution of sodium hypochlorite poses an insignificant risk to the off-site public. However, the chances for accidental spills during transfer from delivery vehicles to the storage tanks should still be reduced as much as possible. Thus, measures to prevent transfer spills are extremely important and would be required as a standard condition in a Safety Management Plan for delivery of sodium hypochlorite (see Condition of Certification **HAZ-3**).

Sulfuric Acid

Sulfuric acid would be stored on site but would not pose a risk of off-site impacts because it has relatively low vapor pressure and thus spills would be confined to the site. Therefore, no further analysis is needed.

Liquefied Petroleum Gas

Liquefied petroleum gas (LPG), also known as propane, poses a fire and/or possible explosion risk because of its flammability. LPG is composed mostly of propane, but may also contain small amounts of ethane, nitrogen, butane, isobutene, and isopentane. It is colorless, odorless, tasteless, and heavier than air. LPG can cause asphyxiation when propane's concentration exceeds 90%. Propane is flammable when mixed in air at concentrations of 2.2 -9.6%, which is also its detonation range. LPG therefore poses a risk of fire and/or explosion if a release was to occur under certain specific conditions and an unconfined vapor cloud of LPG can explode under certain conditions.

LPG will be used in significant quantities only during the pre-startup salt melting and conditioning phase which will last approximately 140 days. The LPG will be stored on-site in two 7,500 gallon mobile tank truck trailers. The risk of a fire and/or explosion on-site can be reduced to insignificant levels through adherence to applicable codes and the development and implementation of effective safety management practices. The National Fire Protection Association codes (NFPA 54, 58 and 85A) require the use of double block and bleed valves for gas shut-off and automated combustion controls, and adherence to DOT pressure vessel design and construction requirements. These measures will significantly reduce the likelihood of an explosion in gas-fired equipment. The Safety Management Plan proposed by the applicant would address both the handling and use of LPG and significantly reduce the potential for equipment failure due to either improper maintenance or human error.

If loss of containment occurs as a result of tank, piping, valve, or other mechanical failure or external forces, significant quantities of LPG could be released rapidly. Such a release could result in a significant fire and/or explosion hazard, which could cause loss of life and/or significant property damage in the vicinity of the leak. However, the

probability of such an event is extremely low if the temporary storage facility is constructed according to present standards. The risk of an accidental is further reduced because the use and storage of propene will occur only during a temporary period lasting approximately 140 days.

The applicant conducted a worst-case offsite consequence analysis (OCA) (CH2MHill 2010a). Staff believes the worst case scenario for an off-site LPG impact is a large rupture of one the tanks caused by an uncontrolled fire nearby that overheats the tank, causing a boiling liquid expanding vapor explosion (BLEVE) of the tank. This worst case scenario would possibly result in a fire ball and explosion. Staff agrees with the applicant's modeling which conforms to CalARP Off-Site Consequence Analysis Guidance document for flammable materials. The resulting maximum distance of significant impact (thermal impact of five kilowatts per square meter) was less than 1,935 feet, a distance which is well within the fenceline. Thus significant impact from the worst case scenario would not extend beyond the facility fence line. The worst case scenario is primarily a safety hazard to on-site employees. The storage facility will be built in conformance with State and Federal regulations to lower the probability of this occurring and Staff considers the potential for such an event to be very low. Staff considers the potential impact to the public as a result of temporary propane storage at RSEP to be less than significant.

Mitigation

Staff believes that this project's use of hazardous materials poses no significant risk but only if mitigation measures are used. These mitigation measures are discussed in this section. The potential for accidents resulting in the release of hazardous materials is greatly reduced by the implementation of a Safety Management Program, which includes both engineering and administrative controls. Elements of facility controls and the safety management plan are summarized below.

Engineering Controls

Engineering controls help prevent accidents and releases (spills) from moving off-site and impacting the community by incorporating engineering safety design criteria into the project's design. Engineering safety features proposed by the applicant include:

- Usage of secondary containment areas surrounding each of the hazardous materials storage areas, designed to contain accidental releases during storage;
- Physical separation of stored chemicals in isolated containment areas, separated by a noncombustible partition in order to prevent the accidental mixing of incompatible materials, which may in turn cause the formation and release of toxic gases or fumes.

Administrative Controls

Administrative controls help prevent accidents and releases (spills) from moving off-site and impacting the community by establishing worker training programs and process safety management programs.

A Worker Health and Safety Program would be prepared by the applicant and include (but not be limited to) the following elements (see the **Worker Safety and Fire**

Protection section in this analysis for specific regulatory requirements):

- Worker training on chemical hazards, health and safety issues, and hazard communication;
- Procedures to ensure the proper use of personal protective equipment;
- Safety operating procedures for the operation and maintenance of systems that use hazardous materials;
- Fire safety and prevention; and
- Emergency response actions including facility evacuation, hazardous material spill cleanup, and fire prevention.

At RSEP, the project owner would be required to designate an individual who would have the responsibility and authority to ensure a safe and healthful workplace. This project health and safety official would oversee the health and safety program and would have the authority to halt any action or modify any work practice in order to protect the workers, facility, and the surrounding community in the event that the health and safety program is violated.

Staff proposes Condition of Certification **HAZ-1** ensures that no hazardous material would be used at the facility except as listed in the AFC and reviewed for appropriateness, unless there is prior approval by the Energy Commission Compliance Project Manager (CPM). Staff reviewed the chemicals and amounts proposed for on-site use, as listed in Table 5.5-3 of the AFC and determined the need and appropriateness of their use. **HAZ-1** also requires changes to the allowed list of hazardous materials and their maximum amounts as listed in **Hazardous Materials Appendix A** to be approved by the CPM. Only those that are needed and appropriate would be allowed to be used. If staff feels that a safer alternative chemical can be used, staff would recommend or require its use, depending upon the impacts posed.

A Hazardous Materials Business Plan (HMBP) would also be prepared by the project owner that would incorporate state requirements for the handling of hazardous materials (RSEP 2009a, section 5.5.2.3.1). Staff proposes Condition of Certification **HAZ-2** which ensures that the HMBP, which includes the Inventory and Site Map, Emergency Response Plan and Owner/Operator Identification, and Employee Training would be provided to the Riverside County Fire Department (RCFD) so that RCFD can better prepare emergency response personnel for handling emergencies which could occur at the facility. In accordance with Condition of Certification **HAZ-3**, the project owner would also be responsible to develop and implement a Safety Management Plan for delivery of liquid hazardous materials. The plan would include procedures, protective equipment requirements, training and a checklist. It would also include a section describing all measures to be implemented to prevent mixing of incompatible hazardous materials. This plan would be applicable during construction, commissioning, and operation of RSEP.

On-site Spill Response

In order to address spill response, the facility would prepare and implement an emergency response plan which includes information on hazardous materials

contingency and emergency response procedures, spill containment and prevention systems, personnel training, spill notification, on-site spill containment, prevention equipment and capabilities, etc. Emergency procedures would be established which include evacuation, spill cleanup, hazard prevention, and emergency response.

A Spill Prevention Control and Countermeasure Plan (SPCC) is required by Federal Regulations (see LORS above) and would be prepared for the petroleum-containing hazardous materials.

The two closest Riverside County Fire stations that would respond to an incident at the proposed project, located adjacent to the former Rice Army Airfield in Rice, CA are Station # 49, located at 43880 Lake Tamarisk, Desert Center, CA. and Station # 43 located at 140 West Barnard Street, Blythe, CA. Riverside County Fire Station 49 is located approximately 70 miles from the project site and the second Riverside County Fire Station is located approximately 75 miles from the proposed site. From the above listed fire stations, the response time for engine 49 is approximately one hour after dispatch. The second unit, engine 43 will respond to the project area in approximately one hour 15 minutes. Riverside County Fire Department Fire Stations are staffed full-time, 24 hours 7 days a week, with a minimum 3 person crew, including paramedics, operating a "Type-1" structural fire fighting apparatus. Each member of the engine company is a certified Emergency Medical Technician and certified to the level of Hazardous Materials First Responder Operational, (HAZ MAT FRO).

In the event of a hazardous materials incident, The Riverside County Fire Department Hazardous Materials Response Team will respond to the project area. The estimated response time is approximately two hours. The Hazardous Materials Response Team #81 is located at 37955 Washington Street in Palm Desert, CA. (Riverside 2010b).

Staff concludes that, given the remote location, the hazardous material response time is acceptable, and that the Riverside County HazMat Team is adequately trained and equipped to respond to an emergency at RSEP in a timely manner. The remote location lengthens the response but, at the same time, eliminates the risk of off-site consequences to the public.

Transportation of Hazardous Materials

Containerized hazardous materials including sulfuric acid, and cleaning chemicals, would be transported to the facility via truck. While many types of hazardous materials would be transported to the site, previous modeling of spills involving much larger quantities of more toxic materials, (aqueous ammonia and 93% sulfuric acid) - two hazardous materials that would be used, stored, and transported at the proposed power plant – has demonstrated that minimal airborne concentrations would occur at short distances from the spill.

During construction and operation of RSEP, staff believes that minimal amounts and types of hazardous materials (paint, cleaners, solvents, gasoline, diesel fuel, motor oil, lubricants, 20% sulfuric acid, and welding gases in standard-sized cylinders) do not pose a significant risk of either spills or public impacts along any transportation route. Staff therefore does not recommend a specific route.

Liquid hazardous materials can be released during a transportation accident, and the extent of their impact in the event of a release would depend on the location of the accident and the rate of vapor dispersion from the surface of the spilled pool. The likelihood of an accidental release during transport is dependent upon three factors:

- The skill of the tanker truck driver;
- The type of vehicle used for transport; and
- Accident rates.

To address this concern, staff evaluated the risk of an accidental transportation release in the project area. Staff's analysis focused on the project area after the delivery vehicle leaves the main interstate highways. One proposed route from the south involves leaving the main interstate highway (I-10) at Desert Center, proceeding northbound on State Route 177, then eastbound on State Route 62 to the RSEP site. An alternate route from the north involves leaving the main interstate highway (I-40) at Needles, proceeding southbound on State Route 95, then westbound on State Route 62 to the RSEP site. The proposed route to the site will not pass in the vicinity of any schools (RSEP 2009a, section 5.5.2.6). Staff believes it is appropriate to rely upon the extensive regulatory program that applies to shipment of hazardous materials on California Highways to ensure safe handling in general transportation (see the Federal Hazardous Materials Transportation Law 49 USC §5101 et seq, the U.S. Department of Transportation Regulations 49 CFR Subpart H, §172-700, and the California DMV Regulations on Hazardous Cargo). These regulations also address issues of driver competence. See AFC section 5.12 for additional information on regulations governing the transportation of hazardous materials.

Seismic Issues

The possibility exists that an earthquake could cause the failure of a hazardous materials storage tank. A quake could also cause the failure of the secondary containment system (berms and dikes), as well as electrically controlled valves and pumps. The failure of all these preventive control measures might then result in a vapor cloud of hazardous materials that could move off-site and impact residents and workers in the surrounding community. The effects of the Loma Prieta earthquake of 1989, the Northridge earthquake of 1994, and the earthquake in Kobe, Japan, in January 1995, heighten concerns about earthquake safety.

Information obtained after the January 1994 Northridge earthquake showed that some damage was caused to several large and small storage tanks at the water treatment system of a cogeneration facility. The tanks with the greatest damage, including seam leakage, were older tanks, while newer tanks sustained lesser damage with displacements and attached line failures. Therefore, staff conducted an analysis of the codes and standards, which should be followed to adequately design and build storage tanks and containment areas that could withstand a large earthquake. Staff also reviewed the impacts of the February 2001 Nisqually earthquake near Olympia, Washington, a state with similar seismic design codes as California. No hazardous materials storage tanks were impacted by this quake. Referring to the sections on **Geologic Resources and Hazards** and **Facility Design** in the AFC, staff notes that the proposed facility would be designed and constructed to the applicable standards of the

2007 California Building (RSEP 2009a, section 2.3.1.1.1). Therefore, on the basis of occurrences at Northridge with older tanks and the lack of failures during the Nisqually earthquake with newer tanks, staff determined that tank failures during seismic events are not likely and do not represent a significant risk to the public.

Site Security

RSEP proposes to use hazardous materials where special site security measures should be developed and implemented to prevent unauthorized access. US EPA published a *Chemical Accident Prevention Alert* regarding site security (EPA 2000a), the U.S. Department of Justice published a special report on Chemical Facility Vulnerability Assessment Methodology (US DOJ 2002), the North American Electric Reliability Corporation (NERC) published *Security Guidelines for the Electricity Sector* in 2002 (NERC 2002), and the U.S. Department of Energy published a draft *Vulnerability Assessment Methodology for Electric Power Infrastructure* in 2002 (DOE 2002). The energy generation sector is one of 14 areas of critical Infrastructure listed by the U.S. Department of Homeland Security. On April 9, 2007, the U.S. Department of Homeland Security published, in the Federal Register (6 CFR Part 27), an Interim Final Rule requiring facilities that use or store certain hazardous materials to conduct vulnerability assessments and implement certain specified security measures. This rule was implemented with the publication of Appendix A, the list of chemicals, on November 2, 2007. Staff believes that all power plants under the jurisdiction of the Energy Commission should implement a minimum level of security consistent with the guidelines listed here.

In order to ensure that this facility (or a shipment of hazardous material) is not the target of unauthorized access, staff's proposed Conditions of Certification **HAZ-4** and **HAZ-5** address both Construction Security and Operations Security Plans. These plans would require the implementation of site security measures that are consistent with both the above-referenced documents and Energy Commission guidelines.

The goal of these conditions of certification is to provide the minimum level of security for power plants needed to protect California's electrical infrastructure from malicious mischief, vandalism, or domestic/foreign terrorist attacks. The level of security needed for this power plant is dependent upon the threat imposed, the likelihood of an adversarial attack, the likelihood of success in causing a catastrophic event, and the severity of consequences of that event.

In order to determine the level of security, the Energy Commission staff used an internal vulnerability assessment decision matrix modeled after the U.S. Department of Justice Chemical Vulnerability Assessment Methodology (July 2002), the NERC 2002 guidelines, the U.S. Department of Energy VAM-CF model, and U.S. Department of Homeland Security regulations published in the Federal Register (Interim Final Rule 6 CFR Part 27). Staff determined that RSEP would fall into the "low vulnerability" category, so staff proposes that certain security measures be implemented but does not propose that the project owner conduct its own vulnerability assessment.

These security measures include perimeter fencing and breach detectors, possibly guards, alarms, site access procedures for employees and vendors, site personnel background checks, and law enforcement contact in the event of a security breach. Site

access for vendors would be strictly controlled. Consistent with current state and federal regulations governing the transport of hazardous materials, hazardous materials vendors would have to maintain their transport vehicle fleets and employ only drivers who are properly licensed and trained. The project owner would be required, through its contractual language with vendors, to ensure that vendors supplying hazardous materials strictly adhere to the U.S. Department of Transportation (DOT) requirements that hazardous materials vendors prepare and implement security plans per 49 CFR 172.800 and ensure that all hazardous materials drivers are in compliance with personnel background security checks per 49 CFR Part 1572, Subparts A and B. The CPM may authorize modifications to these measures, or may require additional measures in response to additional guidance provided by the U.S. Department of Homeland Security, the U.S. Department of Energy, or the North American Electric Reliability Corporation (NERC), after consultation with appropriate law enforcement agencies and the applicant.

Intentional Destructive Acts

Solar generation projects can be the subject of intentional destructive acts ranging from random vandalism and theft to sabotage and acts of terrorism intended to disable the facility. Acts of vandalism and theft are far more likely to occur than sabotage or terrorism. Theft usually involves equipment at substations and switchyards that contain salvageable metal when metal prices are high. Vandalism usually occurs in remote areas and is more likely to involve spontaneous acts such as shooting at equipment.

Pursuant to DOE's policy set out in a December 1, 2006, memorandum, "Need to Consider Intentional Destructive Acts in NEPA Documents," DOE has considered the potential environmental consequences of intentional destructive acts at the Project site. DOE concludes that the risk of damage to the proposed Project from intentional destructive acts would be considered very low, in line with or less than the risk to similar generation facilities in the U.S. Theft or opportunistic vandalism is more likely than sabotage or terrorist acts, which are considered to be a negligible risk.

As indicated above, in order to keep the project infrastructure secure from threats from intentional destructive acts, the project site would be physically secured and staffed. Furthermore, uncontrolled access would be prevented through the use of access controls.

Protection of widely dispersed electrical generation equipment, substations, and thousands of miles of transmission lines from destructive acts is not practical. Damaged equipment and transmission lines may be quickly repaired or replaced in the same manner that storm damaged equipment are returned to service. The results of any such acts could be expensive to repair, but no substantial impacts to continued electrical service would be anticipated. No significant environmental impacts would be expected from physical damage to the proposed Project or from loss of power delivery.

Facility Closure and Decommissioning

The requirements for handling of hazardous materials remain in effect until such materials are removed from the site, regardless of facility closure. Therefore, the facility owners are responsible for continuing to handle such materials in a safe manner, as

required by applicable laws. In the event that the facility owner abandons the facility in a manner that poses a risk to surrounding populations, staff would coordinate with the California Office of Emergency Services, Riverside County Fire Department, and the California Department of Toxic Substances Control (DTSC) to ensure that any unacceptable risk to the public is eliminated.

CEQA Level of Significance

Staff's analysis of impacts associated with the storage, use, and handling of hazardous materials at the proposed RSEP has determined that impacts would be below the level of significance if staff's proposed conditions of certification are adopted.

Reduced Acreage Alternative

The Reduced Acreage Alternative would be 7.2% smaller than the proposed project. It would be located in the same 2,560-acre square-shaped parcel within the larger 3,324-acre ownership property as the proposed project. Although the overall heliostat field distance from the central tower would be reduced, the number of heliostats would remain the same. The heliostat field (plus the evaporation pond and administration areas) would occupy about 1,270 acres instead of the 1,370 acres required for the proposed project. The receiver location would remain the same, with the edges of the field contracting towards the center. The heliostat footprint of the Reduced Acreage Alternative is shown in **Alternatives Figure 2**. The site layout, 653-foot total height of the solar tower and receiver, and transmission interconnection to Western's Parker-Blythe transmission line would be the same as the proposed project. The project's nominal 150 megawatts (MW) generation output would be reduced by approximately two MW.

Similar to the proposed project, the Reduced Acreage Alternative would transmit power to the grid through the planned Western substation to be located adjacent to Western's Parker Blythe 161 kilovolts (kV) transmission line.

The Reduced Acreage Alternative is evaluated in this PSA/DEIS because it would eliminate about 100 acres of the proposed project footprint, reducing impacts to ephemeral washes, the loss of land considered habitat for the state and federally listed threatened desert tortoise and impacts to the historic Rice airfield. The Reduced Acreage Alternative would allow the applicant to contribute clean, renewable energy to help meet the State's energy goals, while minimizing impacts to the desert environment. A limited acreage alternative was suggested in scoping comments.

Under the Reduced Acreage Alternative, the agencies would approve a facility with a 7.2% heliostat field reduction and not the 150 MW project that is proposed.

SETTING AND EXISTING CONDITIONS

The setting for the Reduced Acreage Alternative is the same as for the proposed project except that the heliostat field would occupy 1,270 acres within the 1,370-acre footprint of the proposed project.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

Potential impacts associated with hazardous materials use during construction and operation of the Reduced Acreage Alternative would likely be reduced compared to those estimated for the RSEP as proposed due to the smaller quantities of hazardous materials required. However, staff's analysis has determined that no significant impacts are expected from the storage and use of hazardous materials at the RSEP as proposed. Therefore staff concludes that with respect to hazardous materials handling, the Reduced Acreage Alternative is not preferable over the project as proposed.

NORTH OF DESERT CENTER ALTERNATIVE

The North of Desert Center Alternative would be a 150 MW solar thermal facility located on approximately 2,643 acres of land. It is located along Desert Center Rice Road (State Route 177) east of Kaiser Road, north of Oasis Road, and approximately 1.6 miles north of I-10. The North of Desert Center Alternative is primarily private land with smaller sections of BLM land in the eastern portion of the site. It is largely fallow agricultural land. The existing SCE 161 kV transmission line (from the Blythe-2 substation to the Eagle Mountain-1 substation) that traverses the alternative site would be realigned to roughly follow the site boundary. A new 0.125-mile transmission line (along Osborne Ave.) and substation would interconnect to the realigned SCE line at the northeast boundary of the site. The boundaries and transmission realignment of the North of Desert Center Alternative are illustrated in **Alternatives Figure 2**.

The Desert Center Alternative is evaluated in this PSA/DEIS because it would reduce impacts to cultural resources; the RSEP is located on the historic Rice Army Airfield. The North of Desert Center Alternative would allow the applicant to contribute clean, renewable energy to help meet the State's energy goals, while minimizing impacts to the desert environment.

SETTING AND EXISTING CONDITIONS

The topography of the North of Desert Center Alternative site is essentially flat, as are the immediately surrounding areas. Sensitive receptors are present within the North of Desert Center Alternative and a residential community is located south of the southwest corner of the North of Desert Center Alternative site.

Access to the North of Desert Center Alternative would likely be via Interstate 10 to the Rice Road (SR 177) exit. At Rice Road, transport would turn northeast for approximately two miles through primarily rural residential land.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

Hazardous materials use at the North of Desert Center Alternative, including the quantities handled during transportation and disposal, would be the same as those of the proposed project. As stated in the **Hazardous Materials** section for the proposed project, hazardous materials used during the construction phase of the project would include propane, diesel fuel, mineral insulating oil, lube oil, and small quantities of solvents and paints. No acutely toxic hazardous materials would be used on site during construction, and none of these materials pose a significant potential for off-site impacts

as a result of the quantities on site, their relative toxicity, their physical states, and/or their environmental mobility.

Hazardous materials will be used and stored on site during the operation of the project. As stated in the **Hazardous Materials** section, LPG or propane would be used at the proposed RSEP during commissioning to melt and condition the salt mix that will be used as a heat transfer medium. LPG is composed mostly of propane and butane and poses a fire and explosion risk (not a risk of toxicity) because of its flammability. Up to 15,000 gallons of LPG would be stored in two 7,500-gallon steel truck trailer tanks equipped with secondary containment structures. If loss of containment occurs as a result of tank, piping, valve, or other mechanical failure or external forces, significant quantities of LPG could be released rapidly. Such a release could result in a significant fire and/or explosion hazard, which could cause loss of life and/or significant property damage in the vicinity of the leak. However, the probability of such an event is extremely low if the temporary storage facility is constructed according to present standards. The risk of an accident is further reduced because the use and storage of propane will occur only during a temporary period lasting approximately 140 days.

The applicant conducted a worst-case offsite consequence analysis (OCA) (CH2MHill 2010a). Staff believes the worst case scenario for an off-site LPG impact is a large rupture of one of the tanks caused by an uncontrolled fire nearby that overheats the tank, causing a boiling liquid expanding vapor explosion (BLEVE) of the tank. This worst case scenario would possibly result in a fire ball and explosion. Staff agrees with the applicant's modeling which conforms to CalARP Off-Site Consequence Analysis Guidance document for flammable materials. The resulting maximum distance of significant impact (thermal impact of 5 kW/m²) was less than 1935 feet, a distance which is well within the fence line. Thus significant impact from the worst case scenario would not extend beyond the facility fence line. The worst case scenario is primarily a safety hazard to on-site employees. The storage facility will be built in conformance with State and Federal regulations to lower the probability of this occurring and Staff considers the potential for such an event to be very low.

The predominant risk of storing and using large amounts of LPG at the power plant is that of fire and explosion. Accordingly, the risks are discussed in the **Worker Safety and Fire Protection** section of this SA/DEIS along with staff's proposed mitigation. This discussion would be similar for the North of Desert Center Alternative site, as the climate and fire risk are similar and the North of Desert Center Alternative is closer to a regional fire department.

Transportation of hazardous materials to the North of Desert Center Alternative site would require passing near residences located in Desert Center. The transportation would be on Interstate 10 and Rice Road, not on smaller road with residences.

Comparison to Proposed Project. The hazardous materials that would be used at the North of Desert Center Alternative site would be the same as those used at the proposed RSEP site; however, the North of Desert Center Alternative site has a greater number of sensitive subgroups or residences. As such, the potential impacts at the North of Desert Center Alternative would likely be somewhat greater than at the proposed site. With adoption of the proposed conditions of certification, the Desert Center Alternative would

comply with all applicable laws, ordinances, regulations, and standards (LORS) and result in no significant impacts to the public.

SR 62/RICE VALLEY ROAD TRANSMISSION LINE ALTERNATIVE

The SR 62/Rice Valley Road Transmission Line Alternative would interconnect to Western Area Power Administration's (Western) 161 kV/230 kV Parker-Blythe transmission line at the same location as the proposed project transmission line. This alternative transmission line would exit the power block directly to the east and follow a proposed access road within the heliostat field. The tie-in would then turn north inside the RSEP property boundary and run along the RSEP's circular perimeter road to the north and northwest. At the north end of the heliostat field, the route would traverse the construction laydown area on previously disturbed land over a distance of approximately 500 feet to the southern side of State Route 62. The route would follow State Route 62 approximately 3.8 miles east to the junction of Rice Valley Road. It would then trend south to follow the unpaved Rice Valley Road for 4.1 miles to its juncture with the applicant's proposed new transmission line alignment and continue southeast for 5.4 miles along the proposed alignment to Western's Parker-Blythe transmission line. The SR 62/Rice Valley Road Transmission Line Alternative route is illustrated in **Alternatives Figure 4**.

The SR 62/Rice Valley Road Transmission Line Alternative is evaluated in this SA/DEIS because it would:

1. Avoid the permanent loss of 13.4 acres of foraging and cover habitat for plant and animal species, including the state and federally listed threatened desert tortoise.
2. Avoid the creation of a new 4.6 mile vehicle access route between the proposed solar facility and the proposed junction of the new transmission line access road with the existing Rice Valley road. The proposed new vehicle access route would necessitate additional enforcement and maintenance to prevent unauthorized off-road vehicle access, propagation of new, unauthorized vehicle routes, and consequent habitat damage, soil erosion, and vehicle disturbance.

SETTING AND EXISTING CONDITIONS

The setting for the Reduced Acreage Alternative is the same as for the proposed project except for the rerouting of the transmission lines within the heliostat field.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

Because the amounts and storage locations of hazardous materials would remain the same as for the proposed RSEP project, the impacts and mitigations would also remain the same as for the proposed RSEP project.

Staff's analysis of impacts associated with the storage, use, and handling of hazardous materials at the SR 62/Rice Valley Road Transmission Line Alternative has determined that impacts would be below the level of significance if staff's proposed conditions of certification are adopted.

NO PROJECT/NO ACTION ALTERNATIVE

No Project and No Action on Rice Solar Energy Project transmission line application and interconnection request. No CDCA land use plan amendment.

Under this alternative, the proposed Rice Solar Energy Project would not be approved by the Energy Commission; BLM would not approve the transmission line application and would not amend the CDCA Plan; and Western would not approve the interconnection request. As a result, no solar energy project would be constructed on the project site, BLM would continue to manage the land encompassing the transmission line consistent with the existing land use designation in the CDCA Land Use Plan of 1980, as amended, and Western would continue to operate the Parker Blythe Transmission Line under current conditions.

Because there would be no amendment to the CDCA Plan and no solar project approved for the site under this alternative, it is expected that the site would continue to remain in its existing condition, with no new structures or facilities constructed or operated on the site. As a result, no hazardous materials would be used and no impacts related to the use of hazardous material would occur. In the absence of this project, other renewable energy projects may be constructed to meet State and Federal mandates, and those projects would have similar impacts in other locations.

CUMULATIVE IMPACTS AND MITIGATION

Staff considered the potential for impacts due to a simultaneous release of any of the hazardous chemicals from the proposed RSEP with other existing or foreseeable nearby facilities as listed in the **Cumulative Scenario** section. Because of the small amounts of the hazardous chemicals to be stored at the facility, Staff determined that there was essentially no possibility of producing an offsite impact. Because of this determination, and the additional fact that there are no nearby facilities using large amounts of hazardous chemicals, there is little (if any) possibility that vapor plumes would mingle (combine) to produce an airborne concentration that would present a significant risk.

COMPLIANCE WITH LORS

Staff concludes that construction and operation of RSEP would be in compliance with all applicable LORS for both long-term and short-term project impacts in the area of hazardous materials management.

NOTEWORTHY PUBLIC BENEFITS

Staff has not identified any noteworthy public benefits associated with the use of hazardous materials at the proposed project.

PROPOSED CONDITIONS OF CERTIFICATION/ MITIGATION MEASURES

The following Conditions of Certification meet the Energy Commission's responsibility to comply with the California Environmental Quality Act and serve as staff's recommendations for the Energy Commission to consider in its decision to avoid or reduce the severity of hazardous material-related impacts to less than significant and for the project to conform to all applicable LORS. The identification of relevant and reasonable mitigation measures also conforms to National Environmental Policy Act (NEPA) requirements for BLM's and Western's analysis that can be considered in their Records of Decision.

HAZ-1 The project owner shall not use any hazardous materials not listed in **Hazardous Materials Appendix A**, below, or in greater quantities than those identified by chemical name in **Hazardous Materials Appendix A**, unless approved in advance by the Compliance Project Manager (CPM).

Verification: The project owner shall provide to the CPM in the Annual Compliance Report, a list of hazardous materials contained at the facility.

HAZ-2 The project owner shall concurrently provide a Hazardous Materials Business Plan to the Hazardous Materials Division of the Riverside County Fire Department and the CPM for review. After receiving comments from the Hazardous Materials Division of the Riverside County Fire Department and the CPM, the project owner shall reflect all received recommendations in the final documents. If no comments are received from the county within 30 days of submittal, the project owner may proceed with preparation of final documents upon receiving comments from the CPM. Copies of the final Hazardous Materials Business Plan shall then be provided to the Hazardous Materials Division of the Fire Department for information and to the CPM for approval.

Verification: At least 60 days prior to receiving any hazardous material on the site for commissioning or operations, the project owner shall provide a copy of a final Hazardous Materials Business Plan to the CPM for approval.

HAZ-3 The project owner shall develop and implement a Safety Management Plan for delivery of liquid hazardous materials. The plan shall include procedures, protective equipment requirements, training and a checklist. It shall also include a section describing all measures to be implemented to prevent mixing of incompatible hazardous materials. This plan shall be applicable during construction, commissioning, and operation of the power plant.

Verification: At least sixty (60) days prior to the delivery of any liquid hazardous material to the facility, the project owner shall provide a Safety Management Plan as described above to the CPM for review and approval.

HAZ-4 At least thirty (30) days prior to commencing construction, a site-specific Construction Site Security Plan for the construction phase shall be prepared and made available to the CPM for review and approval. The Construction

Security Plan shall include the following:

1. Perimeter security consisting of fencing enclosing the construction area;
2. Security guards;
3. Site access control consisting of a check-in procedure or tag system for construction personnel and visitors;
4. Written standard procedures for employees, contractors and vendors when encountering suspicious objects or packages on-site or off-site;
5. Protocol for contacting law enforcement, the CPM in the event of suspicious activity or emergency; and
6. Evacuation procedures.

Verification: At least thirty (30) days prior to commencing construction, the project owner shall notify the CPM that a site-specific Construction Security Plan is available for review and approval.

HAZ-5 The project owner shall prepare a site-specific Operation Security Plan for the operational phase and shall be made available to the CPM for review and approval. The project owner shall implement site security measures addressing physical site security and hazardous materials storage. The level of security to be implemented shall not be less than that described below (as per NERC 2002).

The Operation Security Plan shall include the following:

1. Permanent full perimeter fence or wall, at least eight feet high around the Power Block and Solar Field;
2. Main entrance security gate, either hand operable or motorized;
3. Evacuation procedures;
4. Protocol for contacting law enforcement, the CPM in the event of suspicious activity or emergency;
5. Written standard procedures for employees, contractors and vendors when encountering suspicious objects or packages on-site or off-site;
6.
 - a. A statement (refer to sample, attachment "A") signed by the project owner certifying that background investigations have been conducted on all project personnel. Background investigations shall be restricted to ascertain the accuracy of employee identity and employment history, and shall be conducted in accordance with state and federal law regarding security and privacy;
 - b. A statement(s) (refer to sample, attachment "B") signed by the contractor or authorized representative(s) for any permanent

contractors or other technical contractors (as determined by the CPM after consultation with the project owner) that are present at any time on the site to repair, maintain, investigate, or conduct any other technical duties involving critical components (as determined by the CPM after consultation with the project owner) certifying that background investigations have been conducted on contractor personnel that visit the project site.

7. Site access controls for employees, contractors, vendors, and visitors;
8. Closed Circuit TV (CCTV) monitoring system, recordable, and viewable in the power plant control room and security station (if separate from the control room) capable of viewing, at a minimum, the main entrance gate; and
9. Additional measures to ensure adequate perimeter security consisting of either:
 - a. Security guard present 24 hours per day, seven days per week, **OR**
 - b. Power plant personnel on-site 24 hours per day, seven days per week and **one** of the following:
 - 1) The CCTV monitoring system required in number 8 above shall include cameras that are able to pan, tilt, and zoom (PTZ), have low-light capability, are recordable, and are able to view 100% of the perimeter fence to the power block, the outside entrance to the control room, and the front gate from a monitor in the power plant control room; **OR**
 - 2) Perimeter breach detectors **or** on-site motion detectors.

The project owner shall fully implement the security plans and obtain CPM approval of any substantive modifications to the security plans. The CPM may authorize modifications to these measures, or may require additional measures, such as protective barriers for critical power plant components (e.g., transformers, gas lines, compressors, etc.) depending on circumstances unique to the facility or in response to industry-related standards, security concerns, or additional guidance provided by the U.S. Department of Homeland Security, the U.S. Department of Energy, or the North American Electrical Reliability Council, after consultation with appropriate law enforcement agencies and the applicant.

Verification: At least 30 days prior to the initial receipt of hazardous materials on-site, the project owner shall notify the CPM that a site-specific Operations Site Security Plan is available for review and approval. In the Annual Compliance Report, the project owner shall include a statement that all current project employee and appropriate contractor background investigations have been performed, and updated certification statements are appended to the Operations Security Plan. In the Annual Compliance Report, the project owner shall include a statement that the Operations Security Plan includes all current hazardous materials transport vendor certifications for security plans

and employee background investigations.

CONCLUSIONS

Staff's evaluation of the proposed project (with proposed mitigation measures) indicates that hazardous material use, storage, and transportation would not pose a significant impact on the public. Staff's analysis also shows that there would be no significant cumulative impact. With adoption of the proposed conditions of certification, the proposed project would comply with all applicable LORS. Other proposed conditions of certification address the issues of site security matters.

Staff recommends that the Energy Commission impose the proposed conditions of certification, presented below, to ensure that the project is designed, constructed, and operated in compliance with applicable LORS, and would protect the public from significant risk of exposure to an accidental release of hazardous materials. If all mitigation proposed by the applicant and by staff are implemented, the use, storage, and transportation of hazardous materials would not present a significant risk to the public.

Staff concludes that there is insignificant potential for hazardous materials release to have significant impact beyond the facility boundary, and therefore concludes there is also insignificant potential for significant impact to the environment. For any other potential impacts upon the environment, including vegetation, wildlife, air, soils, and water resulting from hazardous materials usage and disposal at the proposed facility, the reader is referred to the **Biology**, the **Air Quality**, the **Soil and Water**, and the **Waste Management** sections of this PSA/DEIS.

Staff proposes five conditions of certification, some of which are mentioned in the text (above), and listed below. **HAZ-1** ensures that no hazardous material would be used at the facility except as listed in the AFC, unless there is prior approval by the Energy Commission Compliance Project Manager. **HAZ-2** ensures that local emergency response services are notified of the amounts and locations of hazardous materials at the facility, **HAZ-3** requires the development of a Safety Management Plan that addresses the delivery of all liquid hazardous materials during the construction, commissioning, and operation of the project would further reduce the risk of any accidental release not specifically addressed by the proposed spill prevention mitigation measures, and further prevent the mixing of incompatible materials that could result in the generation of toxic vapors. Site security during the construction phase is addressed in **HAZ-4** and **HAZ-5** addresses site security during the operational phase.

SAMPLE CERTIFICATION (Attachment "A")

Affidavit of Compliance for Project Owners

I, _____
(Name of person signing affidavit)(Title)

do hereby certify that background investigations to ascertain the accuracy of the identity and employment history of all employees of

(Company Name)

for employment at

(Project name and location)

have been conducted as required by the California Energy Commission Decision for the above-named project.

(Signature of Officer or Agent)

Dated this _____ day of _____, 20 _____.

THIS AFFIDAVIT OF COMPLIANCE SHALL BE APPENDED TO THE PROJECT SECURITY PLAN AND SHALL BE RETAINED AT ALL TIMES AT THE PROJECT SITE FOR REVIEW BY THE CALIFORNIA ENERGY COMMISSION COMPLIANCE PROJECT MANAGER.

**Hazardous Materials
Appendix A**

**Hazardous Materials Proposed for Use
At the
RSEP Power Project**

Anticipated Hazardous Materials Used During Plant Operation

Hazardous Material	Relative Toxicity ¹ and Hazard Class ²	Permissible Exposure Limit	Storage Description; Capacity	Storage Practices and Special Handling Precautions	Possible Uses
Hydrogen	Low toxicity; Hazard class – Flammable gas	None Established	In generator cooling loop and “tube trailer”; total inventory of up to 63,000 SCF (335 pounds) if hydrogen cooled STG is used	Pressure safety tank, crash posts, pressure relief valves	Generator cooling
Sodium Hydroxide, 50% solution	High toxicity; Hazard class – Corrosive	PEL: 2 mg/m ³	Carbon steel tank; 8,500 gallons	Isolated from incompatible chemicals and secondary containment	Water treatment; Condensate polishing
Sodium Hypochlorite, 12.5% solution	High toxicity; Hazard class – Poison-B, Corrosive	Workplace Environmental Exposure Limit (WEEL) - STEL: 2 mg/m ³ PEL: 0.5 ppm (TWA), STEL: 1 ppm as Chlorine TLV: 1 ppm (TWA), STEL: 3 ppm as Chlorine	Plastic tanks; 17,000 gallons total inventory (2 x 8,500 gallons)	Secondary containment	Raw water biocide; Potable water biocide; cooling water biocide
Sulfuric Acid, 29.5% solution	High toxicity; Hazard class – Corrosive, water reactive	PEL: 1 mg/m ³	Contained in batteries; 2,000 gallons total inventory	Isolated from incompatible chemicals and secondary containment	Battery electrolyte
Sulfuric Acid, 93% solution	High toxicity; Hazard class – Corrosive, water reactive	PEL: 1 mg/m ³	Lined, carbon steel tanks; 16,000 gallons total inventory (2 x 8,000 gallons)	Isolated from incompatible chemicals, and secondary containment	Cooling tower anti-scaling (pH control); wastewater neutralization
Carbon Dioxide	Low toxicity; Hazard class – Non flammable gas	TLV: 5,000 ppm (9,000 mg/m ³) TWA	Carbon steel tank, 15 tons maximum onsite inventory	Carbon steel tank with crash posts	Fire suppression

Anticipated Hazardous Materials Used During Plant Operation

Hazardous Material	Relative Toxicity ¹ and Hazard Class ²	Permissible Exposure Limit	Storage Description; Capacity	Storage Practices and Special Handling Precautions	Possible Uses
Lube Oil	Low toxicity Hazard class – NA	None established	Carbon steel tanks, 10,000 gallons in equipment and piping, additional maintenance inventory of up to 550 gallons in 55gallon steel drums.	Secondary containment for tank and for maintenance inventory	Equipment lubrication
Mineral Insulating Oil	Low toxicity Hazard class – NA	None established	Carbon steel transformers; total onsite inventory of 32,000 gallons	Used only in transformers, secondary containment for each transformer	Large capacity transformers
Diesel Fuel	Low toxicity; Hazard class – Combustible liquid	PEL: none established TLV: 100 mg/m ³	Carbon steel tanks (21,000 gallons)	Stored in two 10,000 gallon tanks, secondary containment, plus two day tanks, one for each diesel fire pump.	Emergency generators and fire pumps
Nitrogen	Low toxicity; Hazard class – Non-flammable gas	None established	Carbon steel tank; 7,500 pounds total inventory	Carbon steel tank with crash posts	Blanketing and layup of steam plant
Hydraulic fluid	Low to moderate toxicity; Hazard class – Class IIIB combustible liquid	TWA (oil mist): 5 mg/m ³ STEL: 10 mg/m ³	Carbon steel tanks and sumps; 500 gallons in equipment, maintenance inventory of 110 gallons in 55-gallon steel drums	Found only in equipment, with a small maintenance inventory. Maintenance inventory stored within secondary containment.	Steam turbine controls system

Anticipated Hazardous Materials Used During Plant Operation

Hazardous Material	Relative Toxicity ¹ and Hazard Class ²	Permissible Exposure Limit	Storage Description; Capacity	Storage Practices and Special Handling Precautions	Possible Uses
Water treatment chemical NALCO Tri-Act 1800, or equal Cyclohexylamine (5 – 10%) Monoethanolamine (10 – 30%) Methoxypropylamine (10 – 30%)	High toxicity; Hazard class – Corrosive, Class II Combustible liquid	Cyclohexylamine = TLV: 10 ppm (41 mg/m ³) Monoethanolamine = TLV: 3 ppm (7.5 mg/m ³) TWA: 3 ppm (7.5 mg/m ³) STEL: 6 ppm (15 mg/m ³) Methoxypropylamine = TLV: 5 ppm TWA STEL: 15 ppm	Plastic totes, 2 x 400 gallons each	Inventory management, isolated from incompatible chemicals and secondary containment	Condensate pH management
Water treatment chemical NALCO Elim-Ox Carbonyldiazide (5 - 10%), or equal	Moderate toxicity; Hazard class – Sensitizer	Carbonyldiazide = PEL: none established	Plastic totes, 2 x 400 gallons	Inventory management, isolated from incompatible chemicals and secondary containment	Condensate and feedwater O ₂ management
Water treatment chemical NALCO 3D Trasar 3DT185, or equal Phosphoric Acid (60 -100%)	High toxicity; Hazard class – Corrosive	Phosphoric acid = PEL: 1 mg/m ³ (TWA) TLV: 1 mg/m ³ (TWA), STEL: 3 mg/m ³	Plastic totes, 2 x 400 gallons	Inventory management, isolated from incompatible chemicals and secondary containment	Cooling water corrosion control
Water treatment chemical NALCO 3D Trasar 3DT177, or equal Phosphoric acid (30%)	Moderate toxicity; Hazard class – Irritant	Phosphoric acid = PEL: 1 mg/m ³ (TWA) TLV: 1 mg/m ³ (TWA), STEL: 3 mg/m ³	Plastic totes, 2 x 400 gallons	Inventory management, isolated from incompatible chemicals and secondary containment	Cooling water corrosion control

Anticipated Hazardous Materials Used During Plant Operation

Hazardous Material	Relative Toxicity ¹ and Hazard Class ²	Permissible Exposure Limit	Storage Description; Capacity	Storage Practices and Special Handling Precautions	Possible Uses
Water treatment chemical NALCO 3D Trasar 3DT190, or equal	Low toxicity; Hazard class – Irritant	None established for mixture	Plastic totes, 2 x 400 gallons	Inventory management, isolated from incompatible chemicals and secondary containment	Cooling water scale control
Water treatment chemical NALCO Acti-Brom (R) 7342, or equal Sodium bromide	Low toxicity; Hazard class – Irritant	Sodium bromide = PEL: none established	Plastic totes, 2 x 400 gallons	Inventory management, isolated from incompatible chemicals and secondary containment	Cooling water oxidizing biocide
Water treatment chemical NALCO pHreedom® 5200M, or equal Sodium salt of phosphonomethylated diamine	Low to moderate toxicity; Hazard class – Irritant	Sodium salt of phosphonomethylated diamine = PEL: none established	Plastic totes, 2 x 400 gallons	Inventory management, isolated from incompatible chemicals and secondary containment	Brine concentrator preheater scale control
Water treatment chemical NALCO PCL-1346, or equal	Low toxicity; Hazard class – Irritant	None established for mixture	Plastic totes, 2 x 400 gallons	Inventory management, isolated from incompatible chemicals and secondary containment	Cooling water silica scale control
Water treatment chemical NALCO Permacare (R) PC-7408, or equal Sodium bisulfite	Low toxicity; Hazard class – Irritant	Sodium bisulfite = PEL: none established: TLV: 5 mg/m ³ TWA	Plastic totes, 2 x 400 gallons	Inventory management, isolated from incompatible chemicals and secondary containment	RO system – chlorine scavenger

Anticipated Hazardous Materials Used During Plant Operation

Hazardous Material	Relative Toxicity ¹ and Hazard Class ²	Permissible Exposure Limit	Storage Description; Capacity	Storage Practices and Special Handling Precautions	Possible Uses
Water treatment chemical NALCO BT-3000, or equal Sodium hydroxide Sodium tripolyphosphate	High toxicity; Hazard class – Corrosive	Sodium hydroxide = PEL: 2 mg/m ³ Sodium tripolyphosphate = PEL: none established	Plastic totes, 2 x 400 gallons each	Inventory management, isolated from incompatible chemicals and secondary containment	Boiler drum pH control
Water treatment chemical NALCO 8338, or equal Sodium nitrite Sodium tolytriazole Sodium hydroxide	Moderate toxicity; Hazard class – Toxic	Sodium nitrite = PEL: none established Sodium tolytriazole = PEL: none established Sodium hydroxide = PEL: 2 mg/m ³	Plastic totes, 2 x 400 gallons each	Inventory management, isolated from incompatible chemicals and secondary containment	Closed loop cooling system corrosion inhibitor
Welding gas Acetylene	Moderate toxicity; Hazard class – Toxic	PEL: none established	Steel cylinders; 200 cubic foot each, 800 cubic foot total on site	Inventory management, isolated from incompatible chemicals,	Welding gas
Welding gas Oxygen	Low toxicity; Hazard class – Oxidizer	PEL: none established	Steel cylinders; 200 cubic foot each, 800 cubic foot total on site	Inventory management, isolated from incompatible chemicals	Welding gas
Welding gas Argon	Low toxicity; Hazard class – Nonflammable gas	PEL: none established	Steel cylinders; 200 cubic foot each, 800 cubic foot total on site	Inventory management	Welding gas

Anticipated Hazardous Materials Used During Plant Operation

Hazardous Material	Relative Toxicity ¹ and Hazard Class ²	Permissible Exposure Limit	Storage Description; Capacity	Storage Practices and Special Handling Precautions	Possible Uses
Activated Carbon	Non-toxic (when unsaturated), low to moderate toxicity when saturated, depending on the adsorbed material; Hazard class – combustible solid	TWA (total particulate): 15 mg/m ³ TWA (respirable fraction): 5 mg/m ³ TLV (graphite, all forms except graphite fibers): 2 mg/m ³ TWA	Used in two x 2,000-lb canisters, 4,000 pounds total inventory, no additional storage	No excess inventory stored onsite, prompt disposal when spent	Production of potable water
Herbicide Roundup [®] or equivalent	Low toxicity; Hazard class - Irritant	Isopropylamine salt of glyphosphate = no specific occupational exposure has been established	Brought on site by licensed contractor, used immediately. Maximum of 1 gallon stored onsite.	Inventory management, isolated from incompatible chemicals	Weed management
Soil stabilizer Active ingredient: acrylic or vinyl acetate polymer or equivalent	Non-toxic; Hazard class - NA	None established	Supplied in 55-gallon drums or 400-gallon totes, used immediately. Maximum onsite storage of 55 gal	Inventory management, isolated from incompatible chemicals	Dust control
Aluminum Sulfate (50 wt%), or Ferric Chloride (50 wt%), or Ferric Sulfate (50 wt%)	Moderate Toxicity Hazard class - Corrosive	PEL: 2 mg(Al)/m ³	Plastic tank, 6,000 gallons onsite storage.	Inventory management, isolated from incompatible chemicals	Water treatment system flocculating agent
Sodium Sulfide / Sodium Hydrosulfide	Moderate Toxicity Hazard class -Corrosive	TWA: 10ppm (14mg/m ³) STEL: 15ppm (21mg/m ³)	Brought on site by licensed contractor. No storage onsite	No excess inventory stored onsite, prompt disposal when spent	Water treatment; precipitate heavy metals

Hazardous Materials Used During Plant Operation

Hazardous Material	Relative Toxicity and Hazard Class ²	Permissible Exposure Limit	Storage Description; Capacity	Storage Practices and Special Handling Precautions	Possible Uses
Aqueous Ammonia (19% NH ₃ by weight)	High Toxicity Hazard class - Corrosive Liquid	TWA: 25ppm STEL: 35ppm PEL: 50ppm	Brought on site by licensed contractor. No storage onsite	No excess inventory stored onsite, prompt disposal when spent	Boiler drum, steam, and feedwater conditioner (pH control)
NALCO Permacare PC-33 or equal	Low Toxicity Hazard class – Corrosive Liquid	None established for product. Ingredient limits appear below. ACGIH/TLV: Sodium Hydroxide CEILING: 2 mg/m ³ OSHA/PEL: Sodium Hydroxide CEILING: 2 mg/m ³	110 gallons (55 gallon drums)	Use plastic drums, inventory management and isolate from incompatible chemicals.	RO membrane high pH cleaners
NALCO Permacare PC-77, or equal	Low Toxicity Hazard class – Irritant	None established (contains no hazardous ingredients)	110 gallons (55 gallon drums)	Use plastic drums, inventory management and isolate from incompatible chemicals.	RO membrane low pH cleaners
NALCO Permacare PC-191, or equal	Low Toxicity Hazard class - Irritant	None established (contains no hazardous ingredients)	Plastic Totes, 400 gallon	Inventory management, isolated from incompatible chemicals and secondary containment	RO Antiscalant

Anticipated Hazardous Materials Used During Plant Operation

Hazardous Material	Relative Toxicity ¹ and Hazard Class ²	Permissible Exposure Limit	Storage Description; Capacity	Storage Practices and Special Handling Precautions	Possible Uses
NALCO Permacare PC-11, or equal	High Toxicity Hazard class – Corrosive Liquid	None established for product. Ingredient limits appear below. Manufacturer's Recommendation: Dibromoacetonitrile CEILING: 0.1 ppm (Skin) 2,2-Dibromo-3-nitrilopropionamide CEILING: 2 mg/m ³ AIHA/WEEL: Polyethylene Glycol TWA: 10 mg/m ³	Plastic Totes, 400 gallon	Inventory management, isolated from incompatible chemicals and secondary containment	Membrane cleaner and preservative
Propylene Glycol (Antifreeze)	Low Toxicity Hazard class – NA	None established	Plastic totes, 25 gallons onsite storage	Inventory management, isolated from incompatible chemicals	Antifreeze; closed cooling system anti-corrosive – compatible with different types of metals
<p>¹ Low toxicity is used to describe materials with an NFPA Health rating of 0 or 1. Moderate toxicity is used describe materials with an NFPA rating of 2. High toxicity is used to describe materials with an NFPA rating of 3. Extreme toxicity is used to describe materials with an NFPA rating of 4. ² NA denotes materials that do not meet the criteria for any hazard class defined in the 1997 Uniform Fire Code. ³ Proprietary names are listed to provide indicative chemical product but is not intended to limit supplier, brand or product.</p>

**HAZARDOUS MATERIALS
Appendix B**

**Basis for Staff's Use of 75 Parts Per Million Ammonia
Exposure Criteria**

BASIS FOR STAFF'S USE OF 75 PARTS PER MILLION AMMONIA EXPOSURE CRITERIA

Staff uses a health-based airborne concentration of 75 parts per million (PPM) to evaluate the significance of impacts associated with potential accidental releases of ammonia. While this level is not consistent with the 200-ppm level used by the U.S. Environmental Protection Agency and the California Environmental Protection Agency in evaluating such releases pursuant to the Federal Risk Management Program and State Accidental Release Program, it is appropriate for use in staff's analysis of the proposed project. The Federal Risk Management Program and the State Accidental Release Program are administrative programs designed to address emergency planning and ensure that appropriate safety management practices and actions are implemented in response to accidental releases. However, the regulations implementing these programs do not provide clear authority to require design changes or other major changes to a proposed facility. The preface to the Emergency Response Planning Guidelines states that "these values have been derived as planning and emergency response guidelines, **not** exposure guidelines, they do not contain the safety factors normally incorporated into exposure guidelines. Instead they are estimates, by the committee, of the thresholds above which there would be an unacceptable likelihood of observing the defined effects." It is staff's contention that these values apply to healthy adult individuals and are levels that should not be used to evaluate the acceptability of avoidable exposures for the entire population. While these guidelines are useful in decision making in the event that a release has already occurred (for example, prioritizing evacuations), they are not appropriate for and are not binding on discretionary decisions involving proposed facilities where many options for mitigation are feasible. California Environmental Quality Act requires permitting agencies making discretionary decisions to identify and mitigate potentially significant impacts through feasible changes or alternatives to the proposed project.

Staff has chosen to use the National Research Council's 30-minute Short Term Public Emergency Limit (STPEL) for ammonia to determine the potential for significant impact. This limit is designed to apply to accidental unanticipated releases and subsequent public exposure. Exposure at this level should not result in serious effects but would result in "strong odor, lacrimation, and irritation of the upper respiratory tract (nose and throat), but no incapacitation or prevention of self-rescue." It is staff's opinion that exposures to concentrations above these levels pose significant risk of adverse health impacts on sensitive members of the general public. It is also staff's position that these exposure limits are the best available criteria to use in gauging the significance of public exposures associated with potential accidental releases. It is, further, staff's opinion that these limits constitute an appropriate balance between public protection and mitigation of unlikely events and are useful in focusing mitigation efforts on those release scenarios that pose real potential for serious impacts on the public. Table 1 provides a comparison of the intended use and limitations associated with each of the various criteria that staff considered in arriving at the decision to use the 75-ppm STPEL.

**HAZARDOUS MATERIALS Appendix B Table-1
Acute Ammonia Exposure Guidelines**

Guideline	Responsible Authority	Applicable Exposed Group	Allowable Exposure Level	Allowable* Duration of Exposures	Potential Toxicity at Guideline Level/Intended Purpose of Guideline
IDLH ²	NIOSH	Workplace standard used to identify appropriate respiratory protection.	300 ppm	30 minutes	Exposure above this level requires the use of "highly reliable" respiratory protection and poses the risk of death, serious irreversible injury, or impairment of the ability to escape.
IDLH/10 ¹	EPA, NIOSH	Work place standard adjusted for general population factor of 10 for variation in sensitivity	30 ppm	30 minutes	Protects nearly all segments of general population from irreversible effects.
STEL ²	NIOSH	Adult healthy male workers	35 ppm	15 minutes, 4 times per 8-hour day	No toxicity, including avoidance of irritation.
EEGL ³	NRC	Adult healthy workers, military personnel	100 ppm	Generally less than 60 minutes	Significant irritation, but no impact on personnel in performance of emergency work; no irreversible health effects in healthy adults. Emergency conditions one-time exposure.
STPEL ⁴	NRC	Most members of general population	50 ppm 75 ppm 100 ppm	60 minutes 30 minutes 10 minutes	Significant irritation, but protects nearly all segments of general population from irreversible acute or late effects. One-time accidental exposure.
TWA ²	NIOSH	Adult healthy male workers	25 ppm	8 hours	No toxicity or irritation on continuous exposure for repeated 8-hour work shifts.
ERPG-2 ⁵	AIHA	Applicable only to emergency response planning for the general population (evacuation) (not intended as exposure criteria) (see preface attached)	200 ppm	60 minutes	Exposures above this level entail** unacceptable risk of irreversible effects in healthy adult members of the general population (no safety margin).

1) (EPA 1987) 2) (NIOSH 1994) 3) (NRC 1985) 4) (NRC 1972) 5) (AIHA 1989)

* The (NRC 1979), (WHO 1986), and (Henderson and Haggard 1943) all conclude that available data confirm the direct relationship to increases in effect with both increased exposure and increased exposure duration.

** The (NRC 1979) describes a study involving young animals, which suggests greater sensitivity to acute exposure in young animals. The WHO (1986) warned that the young, elderly, asthmatics, those with bronchitis, and those that exercise should also be considered at increased risk based on their demonstrated greater susceptibility to other non-specific irritants.

LAND USE, RECREATION, AND WILDERNESS

Testimony of Shaelyn Strattan

This section provides the California Energy Commission's staff analysis of Land Use, Recreation, and Wilderness impacts of the Rice Solar Energy Project (RSEP), prepared jointly with the Bureau of Land Management (BLM) and Western Area Power Administration (Western), and describes recommended mitigation for those impacts, in accordance with the requirements of the California Environmental Quality Act (CEQA) and the National Environmental Policy Act (NEPA). The staff conclusions and recommendation of feasible mitigation measures/conditions of certification conform to CEQA requirements for the Energy Commission's analysis. The identification of feasible mitigation measures is consistent with NEPA requirements, as applicable for BLM and Western. This analysis is not the final decision document for BLM, Western, or the Energy Commission.

SUMMARY OF CONCLUSIONS

The proposed Rice Solar Energy Project would be located on land within the California Desert Conservation Area (CDCA), as amended by the Northern and Eastern Colorado Desert Coordinated Management (NECO) Plan. The project footprint would include approximately 1,410 acres of privately owned property and 99 acres of "Multiple-Use Class M" (MUC-M) public (federal) lands, managed by the U.S. Bureau of Land Management (BLM), on a 2,560-acre project site. Siting of electrical generation plants on Class M lands requires compliance with federal, state, and local laws and the NEPA environmental review process.

The proposed project would also require BLM approval of an Amendment to the CDCA Plan and issuance of a Right-of-Way (ROW) grant for use of approximately 99 acres: a 10-mile long corridor, 150 feet wide, and a three acre plot for the interconnection substation. The applicant has submitted an initial ROW application with the approximate acreage and alignment, which would be modified to include only the final project footprint prior to issuance.

The proposed project would not:

- Result in the loss or conversion of Farmland or forest land to non-agricultural uses.
- Conflict with or result in a change to any agricultural zoning or existing Williamson Act contracts.
- Conflict with existing zoning for, or cause rezoning of, forest land, timberland, or timberland zoned Timberland Production.
- Directly or indirectly divide an established community.
- Induce substantial population growth in the project area.
- Impact airport operations.

The proposed project would have a less than significant impact on:

- Wilderness and recreation areas.

- Permanent loss of lands within a portion of the proposed project footprint for agriculture, natural resources, and recreation.
- Recreational use of and access to a portion of the proposed project site and surrounding BLM-managed federal lands.
- The historic significance and potential National Register eligibility of Camp Rice.
- Future land use and development.

The proposed project would have a less than significant impact, with full implementation of the applicable conditions of certification, on:

- Agricultural use (grazing) and access in an established federal rangeland area within the CDCA.
- Consistency with most applicable land use plans, policies, and regulations of an agency with jurisdiction, or that would normally have jurisdiction, over the project.

The proposed project would have the following significant/substantial, unavoidable impacts :

- Result in a loss of scenic character, both project-specific and cumulative.
- Result in the loss of a historic resource with potential National Register eligibility (Rice Army Airfield) (NEPA).
- Contribute substantially to cumulative loss of visual/scenic character.

The proposed project would not be consistent with the following laws, ordinances, regulations, and standards, even with implementation of proposed conditions of certification:

- Riverside County General Plan Land Use Element policies: LU 6.1, LU 13.1, LU 13.3, LU 20.1, LU 20.2, LU 20.4, LU 30.1. Inconsistency with these General Plan policies are primarily the result of the significant impacts to visual/scenic impacts identified above.
- Riverside County General Plan Multipurpose Open Space Element policy OS 21.1

INTRODUCTION

The California Energy Commission (hereafter referred to as “staff”), in cooperation with the Bureau of Land Management (BLM) and Western Area Power Administration (Western), have reviewed the proposed Rice Solar Energy Project (RSEP or “proposed project”), in accordance with the requirements of the California Environmental Quality Act (CEQA) and the National Environmental Policy Act (NEPA).

The Land Use section of this document addresses project compatibility with existing or reasonably foreseeable land uses; consistency with applicable laws, ordinances, regulations, and standards (LORS); and potential project-related direct, indirect, and cumulative environmental effects. It discusses land use issues, including concerns related to agriculture, recreation, wilderness, wild horse and burro, and rangeland

resources. It also recommends mitigation/conditions of certification intended to reduce or eliminate impacts associated with any potentially significant environmental effects.

In addition to the effects associated with the land use component of this document, an energy generating system and its related facilities generally has the potential to create environmental impacts to other natural and human resources. Issues related to these resource areas are discussed in detail in separate sections of this document.

BLM manages the land that would be used for the proposed transmission and utility corridors. The BLM California Desert Conservation Area (CDCA) Plan of 1980 establishes management guidelines, procedures, and policies for the public lands impacted by the proposed project.

METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

Given the respective power plant licensing and land jurisdictions of the California Energy Commission and U.S. Bureau of Land Management (BLM), and the transmission interconnection with Western, analysis of potential project impacts must comply with both CEQA and NEPA requirements. Because this document is intended to meet the requirements of both NEPA and CEQA, the methodology used for determining environmental impacts of the proposed project includes a consideration of guidance provided by both laws.

Both CEQA and NEPA require the Lead Agency(ies) to determine potentially significant project-related impacts. That significance is determined as part of the CEQA analysis in the Environmental Impact Report (EIR) or equivalent document. With NEPA, the potential environmental effects are analyzed in the EIS, not with regard to their significance, but rather in terms of the nature and degree of their potential impact.

CEQA requires a Lead Agency to identify the criteria used to determine the significance of potential project-related impacts. A significant impact is defined by CEQA as “a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project”. A social or economic change related to a physical change may be considered in determining whether the physical change is significant. However, an economic or social change by itself shall not be considered a significant effect on the environment. (CCR 2009, §15382).

In comparison, NEPA defines ‘significance’ as effects or issues of sufficient context and intensity that an EIS is required. ‘Context’ refers to the effect of the project on society as a whole (human, national), the affected region, the affected interests, and the locality. ‘Intensity’ addresses the severity of identified direct, indirect, and cumulative effects. The significance of an issue or effect under NEPA is not declared within the EIW. As with CEQA, economic or social effects are not intended, by themselves, to require preparation of an environmental impact statement (40 CFR 1508.14). By electing to prepare an EIS, Western (as the NEPA lead agency) has deemed that the project has the potential to result in a significant effect on the environment.

THRESHOLDS OF SIGNIFICANCE (CEQA) ¹

The determinations of significance under CEQA, as identified by the Energy Commission in this section, are based on scientific and factual data related to issues addressed in Appendix G of the CEQA Guidelines, performance standards, thresholds identified by the Energy Commission staff, and thresholds recommended by other public agencies or subject experts, as supported by substantial evidence. (CCR 2009)² Thresholds are quantified, where feasible, and supported by specific evidence.

ISSUES

Issues considered for impacts of significance, under CEQA and/or NEPA, include the following:

Agriculture, Forest, and Rangelands

Would the project:

- Convert Prime Farmland, Unique Farmland, Farmland of Statewide Importance, as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Resources Agency, or Farmland of Local Importance to non-agricultural use³? (CEQA)
- Conflict with existing agricultural zoning, agricultural use, or a Williamson Act contract? (CEQA)
- Conflict with existing zoning for, or cause rezoning of, forest land [as defined in PRC §12220(g)], timberland (as defined by PRC §4526), or timberland zoned Timberland Production [as defined by GC §51104(g)]? (CEQA)
- Result in the loss of forest land or conversion of forest land to non-forest use? (CEQA)
- Involve other changes in the existing environment which, due to their location or nature, could result in conversion of Farmland to non-agricultural uses⁴ or forest land to non-forest use? (CEQA)
- Disrupt activities or substantially reduce the agricultural resource value of established federal rangelands within the California Desert Conservation Area? (NEPA)

¹ A threshold of significance is an identifiable quantitative, qualitative, or performance level of a particular environmental effect. Effects exceeding that threshold would be considered significant. (CCR 2009, §15064.7)

² Pursuant to CEQA Guideline Amendments, adopted December 30, 2009; effective March 18, 2010.

³ FMMP defines "land committed to non-agricultural use" as land that is permanently committed by local elected officials to nonagricultural development by virtue of decisions which cannot be reversed simply by a majority vote of a city council or county board of supervisors.

⁴ Non-agricultural uses in this context refers to land where agriculture (the production of food and fiber) does not constitute a substantial commercial use.

Wilderness and Recreation

Would the project:

- Increase the use of existing neighborhood and regional parks or other recreational facilities, such that substantial physical deterioration of the facility would occur or be accelerated? (CEQA)
- Include recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment? (CEQA)
- Directly or indirectly disrupt activities in established federal, state, or local recreation and/or wilderness areas? (NEPA)
- Substantially reduce the scenic, biological, cultural, geologic, or other important resource value of federal, state, local, or private recreational facilities or wilderness areas? (NEPA)
- Directly, indirectly, or cumulatively affect the wilderness qualities of size, naturalness, or outstanding opportunities for solitude or primitive and unconfined recreation of a wilderness area or wilderness study area; or change the characteristics of a wilderness study area, such that it would not contain the qualities necessary for it to be considered for future designation as wilderness? (NEPA)

Land Use Compatibility and LORS Compliance

Would the project:

- Directly or indirectly divide an established community or disrupt an existing or approved land use? (CEQA & NEPA)
- Induce substantial population growth in an area, either directly or indirectly? (CEQA)
- Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction, or that would normally have jurisdiction, over the project adopted for the purpose of avoiding or mitigating environmental effects? (CEQA & NEPA)
- Conflict with any applicable habitat conservation plan, natural community conservation plan, or biological opinion? (CEQA & NEPA)

Cumulative Land Use Effects

Would the project:

- Result in incremental impacts that, although individually limited, are cumulatively considerable when viewed in connection with other project-related effects or the effects of past projects, other current projects, and probable future projects?⁵ (CEQA & NEPA)

⁵ Cumulative impacts refer to two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts. The individual effects may be changes resulting from a single project or a number of separate projects and can result from individually minor, but collectively significant actions taking place over a period of time (CEQA Guidelines §15355; 40 CFR 1508.7).

Laws, Ordinances, Regulations and Standards (LORS)

LAND USE Table 1 provides a general description of the land use LORS applicable to the proposed project, all alternatives, and surrounding lands. LORS specific to a single alternative are addressed in the analysis for that alternative.

**LAND USE Table 1
Laws, Ordinances, Regulations, and Standards (LORS)**

Applicable LORS	Description
Federal	
<u>California Desert Conservation Area (CDCA) Plan, 1980 as Amended; 1999.</u>	The CDCA Plan is a comprehensive, long-range plan for over 12 million acres of public California Desert lands, including the Mojave, Sonoran Desert, and a small portion of the Great Basin, with goals and specific actions for management, use, development, and protection of the lands and their resources. The Plan is administered by the BLM and is based on the concepts of multiple use, sustained yield, and maintenance of environmental quality. All project sites are located within the CDCA boundaries and all but one site are on public lands, and are, therefore, subject to the CDCA Plan.
Northern and Eastern Colorado Desert Coordinated Management Plan (NECO)	NECO is an amendment to the CDCA land use plan and specific management prescriptions for species and habitats on federal lands, providing in particular for the recovery of the desert tortoise; integrating land management plans for conservation of species and habitats among the three federal land managing agencies; and providing a landscape approach to managing desert ecosystems.
State	
Public Resources Code §25529 (Public Access - Warren Alquist Act)	Requires the Energy Commission to impose a condition of certification requiring the project owner to acquire and maintain a public access/use area when a proposed facility would be located in the coastal zone or areas with recreational, scenic, or historic value. It also requires that any facility be set back from the coast or shoreline of any major body of water to permit reasonable public access and to protect scenic and aesthetic values.
Local	
<u>Riverside County General Plan (2003), as amended through December 2008</u>	The Riverside County General Plan provides policy direction for the entire unincorporated portion of the County and for 19 sectors of the County in the form of Area Plans. A large portion of the eastern desert area of the County, including the project site, is not covered by area plans and thus falls under direction of the countywide policies.
Chapter 3 – Land Use Element	This element addresses policies that direct land use and development in the County: policies that apply countywide and those that are unique to a specific region. Countywide policies are applicable to the entire unincorporated area, are contained in the General Plan and reflected on the General Plan Land Use Map. Land use designations are included in this element.
-Open Space/Rural (OS-RUR) Land Use Designation	The OS-RUR land use designation applies to remote, privately owned open space areas with limited access and a lack of public services. The designation is intended to ensure that development does not adversely impact the open space and rural character of the surrounding area.
-Eastern Riverside County Desert Areas (Non-Area Plan)	The intent of this section of Chapter 3 is to preserve the unique and spectacular open space character of the desert region of eastern Riverside County that is not a part of any Area Plan, and to maintain those existing rural and mineral resource land uses scattered throughout the area.

Applicable LORS	Description
Chapter 5 – Multipurpose Open Space Element	Addresses county policies regarding renewable and non-renewable County resources. Conservation of these natural resources applies to water, agricultural resources, forests, vegetation, mineral, and energy resources.
<p data-bbox="201 296 488 443"><u>Riverside County Zoning Ordinance #348, amended through Ord. #348.4647 (August 20, 2009)</u></p> <p data-bbox="201 506 472 625">Article XV, §§15.1 and 15.2 Controlled Development Areas (W-2) Zoning District</p> <p data-bbox="201 657 464 772">Article XVb, §§15.200 and 15.201 Natural Assets (N-A) Zoning District</p> <p data-bbox="201 810 483 867">Article XVII §18.33 Temporary Use of Land</p>	<p data-bbox="511 296 1365 470">This title is adopted to promote and protect the public health, safety, and welfare through the orderly regulation of land uses throughout the unincorporated area of Riverside County; provide economic and social advantages resulting from an orderly planned use of land resources; and encourage and guide development consistent with the Riverside County General Plan.</p> <p data-bbox="511 506 1409 562">This section identifies uses permitted and development standards in the Controlled Development Areas zoning district. The project site is zoned W-2.</p> <p data-bbox="511 657 1357 743">This section identifies uses permitted and development standards in the Natural Assets zoning district. Some of the properties surrounding the project site are zoned N-A.</p> <p data-bbox="511 810 1393 896">Allows the temporary use of land in any zone classification for uses related to the construction of public utilities and other permitted activities for longer than six months.</p>
<u>Riverside County Code, Ordinance 457.102 (Building Codes & Fees)</u>	Identifies minimum building standards for all grading, buildings, and structures, or parts thereof, in the unincorporated areas of the County of Riverside, except as excluded under federal and/or state jurisdiction.
<u>Riverside County Code, Ordinance 460.151, §18.7 (Merging of Contiguous Parcels)</u>	Establishes criteria and provides a means to merge four or fewer contiguous parcels without reversion to acreage.
<u>Riverside County Ordinance 659, as amended through 659.8 (Development Impact Fees)</u>	Establishes criteria and fees required of development projects to allow the County to construct/acquire the needed public facilities to support development and preserve open space, wildlife, and their habitats.
<u>Riverside County Ordinance 859, as amended through 859.2 (Water Efficient Landscape Requirements)</u>	Incorporates the requirements of the California Water Conservation in Landscaping Act of 2006 and CCR Title 23, Division 2, Chapter 2.7 (§§490-495)

PROPOSED PROJECT (ALTERNATIVE 1)

SETTING/AFFECTED ENVIRONMENT

The proposed project is a 150-megawatt (MW) concentrating solar thermal power project with a central receiver tower, sun-tracking heliostat field, and an integral thermal storage for the liquid salt-based system. The power block and solar arrays would cover approximately 1,410 acres of a 2,560-acre project site, immediately south and adjacent to State Route (SR) 62, at milepost 109, approximately 20 miles east of the SR62/177 intersection, and 15 miles west of Vidal Junction, in unincorporated Riverside County.

The generating facility would be constructed on privately owned land and connected to the Western's Parker-Blythe transmission line by a 10.0-mile-long generation tie-line. The transmission line would be situated primarily on BLM-managed public lands, although it would cross a portion of two privately-owned parcels (see **Land Use Figure 1**).

The project's power block and solar arrays would be located on the site of the Rice Army Air Field and a portion of Camp Rice, a World War II (WWII) desert training base that was part of the infantry and artillery Desert Training Center, California-Arizona Maneuver Area (DTC/C-AMA). It was used by General George S. Patton, Jr., from 1942-1944 to prepare American soldiers for combat in the North African desert. This location, a municipal airfield prior to WWII, reverted to civilian/public airport status again about 1949, then to a private airfield around 1952. Apparently abandoned between 1955-1958, the airport continued to be used sporadically by private pilots until the runways became unsafe. (ARPT 2009a) To the east, Camp Rice (Rice Divisional Camp) housed the 5th Armored Division during its training at the DTC/C-AMA and maintained a large quartermaster depot at that location. (CSMD 2010) The area was also used for Joint Exercise Desert Strike in 1964 (SR2009a). Little remains of Camp Rice or the Rice Army Airfield, aside a few foundations, concrete pads, and defunct runways. Although the outline of both the airport and Camp Rice can still be easily discerned from the air, the sense of place is deteriorating at ground level. (See **Cultural Resources** section for additional information.)

The site is generally flat, with elevations ranging from about 720 feet (220 meters) above sea level (ASL) at the southern boundary to approximately 820 feet (250 meters) ASL in the north, along SR 62. Native plant revegetation is sparse to moderate and interrupted by the remains of the asphalt, gravel, concrete pads, foundations, runways, and taxiways. However, despite previous disturbance, the site supports a diverse plant and animal ecosystem, primarily creosote bush-bursage desert scrub and burrowbush, providing habitat for a variety of common desert species and may also support some special status species (see **Biological Resources** section). A number of small, dry desert washes traverse the project area, but no large ephemeral washes are present. There are no structures on the site, except for a few decaying foundations stemwalls, and no active use. The proposed project site can best be described as extensively disturbed land that has been unused for about 50 years and is gradually reverting to desert.

The northern portion of the proposed project footprint is bounded by SR 62, the Arizona and California Railroad short line, and the Colorado River Aqueduct. As noted above, the former Camp Rice is situated along a portion of the eastern project site boundary, with some private land directly south, and BLM-managed public lands surrounding the remainder of the site. The proposed transmission line corridor would extend southeast for approximately 10 miles, across BLM-managed public lands and two privately owned parcels, connecting with the Western Parker-Blythe transmission line within the existing Western/BLM right-of-way (ROW).

Parcels to be included in the site for the generating facility are indicated in **Land Use Table 2** below.
